- Subject ML 857 shifted from a A*6802 DTVLEDINL and B35 (H/N)PDIVIYQY response prior to seroconversion to a B35 PPIPVGDIY and B35 VPLRPMTY response post-seroconversion, and the loss of the pre-seroconversion response was not due to sequence variation within these epitopes.
- Subject ML 1203 started with CTL responses to A*6802 DTVLEDINL and B7 FPVTPQVPLR prior to seroconversion, and upon seroconversion acquired additional responses to A*6802 ETAYFILKL which became dominant, B7 TPGPGV/IRYPL, B7 IPRRIRQGL, and B7 SPRTLNAWV.
- Subject ML 1707 started with a CTL response to A*6802 DTVLEDINL prior to seroconversion, and switched to

A*6802 ETAYFILKL and A24 RDYVDRFFKTL post-seroconversion, and the loss of the pre-seroconversion response was not due to sequence variation within the epitope.
- Subject ML 1830 made no detectable response prior to seroconversion, but responded to A*6802 DTVLEDINL and A*6802 ETAYFILKL post-seroconversion.

Epitope name EW9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B*44)
Country Australia, Canada, Germany, United States
Keywords HLA associated polymorphism
References Brumme *et al.* 2008a

- 98 newly infected patients were studied to track early host HLA and Gag/Pol/Nef epitope immune responses' association with viral evolution. Response hierarchies were the same as those for later infection, and 50% of the most rapidly substituting epitopes were restricted by protective HLA, e.g. Gag B*57-associated mutations which were the most rapidly reverting upon transmission to a non-B*57-host. While there are great differences in mutation rates and reversions across the HIV proteome, most early viral change is driven by immune pressure.
- HLA-driven epitope evolution was seen in 80% of published CTL epitopes.
- HLA-B*44-associated substitutions within optimally defined epitope EEMNLPGRW are at positions E2 and N4, EeMnLPGRW.

Immunogen HIV-1 infection
Species (MHC) human (B*4402)
Country Australia
Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, HLA associated polymorphism
References Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore et al., Science 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- The fourth position of the epitope EEMnLPGRW has a mutational pattern that is correlated the host carrying HLA B*4402.

Epitope EEMNLPGRW
Epitope name EW9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B18, B40, B44)
Country Germany
Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, variant cross-recognition or cross-neutralization, immune evasion, HLA associated polymorphism, drug resistance
References Mueller *et al.* 2007

- To assess HIV-1-specific CTL influence on development and patterns of drug resistance in protease (PR) 94 HLA-typed patients were analyzed. 10 new CTL epitopes were defined statistically and experimentally, and 26 correlations (positive and negative) between HLA class-I alleles and PR mutations - some leading to escape mutations - were detected, demonstrating that CTL epitopes can be predicted based on HLA-amino acid substitution associations.

- Some patient CTL escape mutations were detectable by other CTLs of the same patient. Correlations between resistance mutations, polymorphisms and specific PR inhibitors were not detected.
- HLA-B had the strongest impact on PR sequence change, though HLAs-A and -C also had some impact.
- The authors suggest that CTL escape is active in developing drug-resistance related polymorphisms as well as major and minor mutations in HIV-1 infected persons.
- HIV-1 subtype breakdown in this cohort was follows - 83/94 patients infected with subtype B virus, 3 with subtype C, 4 CRF01_AE, 1 CRF03_AB, 1 CRF15_01B and 2 subtype Ds.
- This highly immunogenic index epitope, EEMNLPGRW, EW9, developed variants EEiNLPGRW, EW9 M/I, EEMdLPGRW, EW9 N/D, EdMNLPGRW, EW9 E/D, EdiNLPGRW, EW9 D/I, EEMNLPGkW, EW9 R/K, EEMNLsGRW, EW9 P/S. E35D and P39S mutants were located in the previously reported HLA-B44 restricted epitope EEMSLPGRW (EW9). The correlation between the minor drug mutation E35D and HLA-B44 was strong, while that of -B44 with P39S was weak. E35D mutations induced a strong decrease in CTL recognition, but few patient samples did mount specific responses against it giving a negative correlation between this mutation and HLA-B44. A novel association between the E35D mutant and HLA-B18 was also found.
- Cross-reactivity of CTL recognition of EW9 and variants occured for most patients. This showed that cells from several patients mount oligoclonal CTL responses, indicating immune system reactions to escape by recruitment of CTLs with new TCR specificities. On the other hand, most patients showed mutually exclusive recognition of variant epitopes containing either E35D or E35E; HLA-B44 subtypes and other factors tested could not explain this phenomenon.
- EW9 epitope and variant peptides include the S37N substitution when compared to HXB2 strain sequences.
- HLA-restrictions to this epitope were HLA-18, -40, -44.

Keywords rate of progression, escape, immune evasion
References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

Assay type Intracellular cytokine staining
Keywords epitope processing, vaccine-specific epitope characteristics, immunodominance, variant cross-recognition or cross-neutralization, vaccine antigen design
References Singh & Barry 2004

- When A*0201-C3H/J transgenic mice were immunized with plasmids encoding wild-type gag-pol, codon-optimized (CO) gag-pol, and an expression library vaccine expressing 16 fragments of gag-pol fused with ubiquitin for proteosome targeting (ELI), the ELI vaccine produced up to 10-fold higher CD8 T-cell responses than the other two vaccines. In contrast to the wt and CO vaccines, which tended to augment only immunodominant responses, boosting with the ELI vaccine resulted in many CD8 responses against variant epitopes from different HIV-1 clades, and against drug-resistant variants.
- The drug resistant variant of this epitope, kViVgiggfi, was tested. WT and CO vaccines produced low level CD8+ T-cell responses against the B clade form as well as against drug resistant variant, but the ELI vaccine produced much more intense responses against both the WT and the variant, including after boosting.

HXB2 Location Protease (45–54)
Author Location Pol (125–134)
Epitope KMIGGIGGFI
Immunogen HIV-1 infection
Species (MHC) human (A2 supertype)
Keywords supertype, rate of progression
References Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind three of the five HLA-A2 supertypes alleles (A*0201, A*0202, A*0203, A*0206 and A*6802).

HXB2 Location Protease (45–54)

Country South Africa
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining
Keywords epitope processing, immune evasion, viral fitness and reversion, HLA associated polymorphism
References Honeyborne *et al.* 2007

- To determine whether HLA-B*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.

Epitope RQYDQILIEI
Epitope name RI10
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B*13)
Country Australia, Canada, Germany, United States
Keywords escape, HLA associated polymorphism
References Brumme *et al.* 2008a

- 98 newly infected patients were studied to track early host HLA and Gag/Pol/Nef epitope immune responses' association with viral evolution. Response hierarchies were the same as those for later infection, and 50% of the most rapidly substituting epitopes were restricted by protective HLA, e.g. Gag B*57-associated mutations which were the most rapidly reverting upon transmission to a non-B*57-host. While there are great differences in mutation rates and reversions across the HIV proteome, most early viral change is driven by immune pressure.
- HLA-driven epitope evolution was seen in 80% of published CTL epitopes.
- HLA-B*13-associated substitutions within optimally defined epitope RQYDQILIEI are at positions L7 and E9, RQYDQIlIeI. RI10 was the 5th most rapidly escaping epitope.

Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords TCR usage, characterizing CD8+ T cells
References Yang *et al.* 2005a

- CTL responses were evaluated in identical twins infected with HIV-1 from the same blood source. Targeting of the CTL was similar in the 2 patients, while their TCR profiles were highly dissimilar. It is suggested that CTL targeting is predominately genetically determined, while T-cell generation is a stochastic process; the responding CTLs differ at the TCR molecular level, leaving the viral escape and CTL efficacy unpredictable.
- HKAIGTVLVGPTPVN was the immunodominant epitope in each twin, but was recognized by T cells with distinctly different TCRs. The epitope was not defined within the epitope. The twins had very different patterns of HIV evolution in this region, with one carrying HKveGsVLiGPTPVN and the other HKAIGaVLiGPTPVN.

References Balamurugan *et al.* 2008

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.
- CTL immune response to consensus sequence HKAIGTVLVGPTPVN was elicited in subject 00015. Consensus epitope of subject 00015 was qKAIGTVLVGPTPVN and of subject 00016 was qHKAIGTVLVGPTPVd.

References Singh & Barry 2004

- When A*0201-C3H/J transgenic mice were immunized with plasmids encoding wild-type gag-pol, codon-optimized (CO) gag-pol, and an expression library vaccine expressing 16 fragments of gag-pol fused with ubiquitin for proteosome targeting (ELI), the ELI vaccine produced up to 10-fold higher CD8 T-cell responses than the other two vaccines. In contrast to the wt and CO vaccines, which tended to augment only immunodominant responses, boosting with the ELI vaccine resulted in many CD8 responses against variant epitopes from different HIV-1 clades, and against drug-resistant variants.
- The drug resistant variant of this epitope,vlvgptpTnV, was tested. WT and CO vaccines produced low level CD8+ T-cell responses against the B clade form as well as against drug resistant variant, but the ELI vaccine produced much more intense responses against both the WT and the variant, including after boosting.

Species (MHC) transgenic mouse (A*0201)
Assay type CD8 T-cell Elispot - IFNγ, HLA binding

Keywords vaccine-specific epitope characteristics, drug resistance
References Boberg *et al.* 2006

- Binding of a protease epitope and its variants caused by drug-resistance mutations to HLA-A0201 and CTL responses in transgenic mice immunized with this epitope were analyzed. It was found that both the wild-type and resistance variants of the epitope bound well to HLA-A0201 and were strongly immunogenic in HLA-A0201 transgenic mice. Immunological cross-reactivity between different variants of the peptide was observed, suggesting that immunization with drug-resistance mutated epitopes could induce a broad immune response, which may cause a better outcome of antiretroviral therapy in HIV-1 infected individuals.
- An interesting epitope from the HIV-1 protease (PR) protein was found VLVGPTPVNI, and mutant variants - VLVGPTPaNI, VLVGPTPfNI, VLVGPTPVNv, VLVGPTPfNv. The epitope, VLVGPTPVNI, and its drug-induced mutant version VLVGPTPfNv, were studied and were able to elicit responses both by peptide constructs and multi-CTL epitope constructs.

References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope LVGPTPVNI was predicted to be restricted by HLA A*0201, A*0202, A*0205,A*0209, B*1501 and B*1516.

Immunogen HIV-1 infection
Species (MHC) human (A2)
Assay type Intracellular cytokine staining, Chromium-release assay
Keywords HAART, ART, escape
References Karlsson *et al.* 2003

- This epitope contains two positions that are commonly associated with protease inhibitor escape, lvgptpAni (V82A) and lvgptpvnV (I84V). 29 HIV-1 infected patients (15 were HLA-A2+) with a history of protease inhibitor failure were screened for mutations within the protease gene and CD8+ T cells recognition of the wt and V82A variant peptides. CTL pressure alone, despite high functional avidity, did not drive the V82A substitution. Suprisingly V82A was found more frequently among HLA-A2- individuals (10/14) than HLA-A2+ (7/15), despite the mutation conferring not only drug resistance but CTL escape.
- 8/15 HLA-A2+ patients carried had a Val at position 82; 7/8 of these recognized the WT peptide, but only 3/8 could also recognize V82A.
- 7/15 had the V82A substitution; 2/7 recognized the wt and the V82A mutation, 1/7 recognized only the peptide with the V82A substitution.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords HAART, ART, escape, immunotherapy, variant cross-recognition or cross-neutralization
References Mason *et al.* 2004

- Accumulation of specific antiretroviral drug-resistance mutations in Pol gene was shown to sustain and even enhance the antigenicity and immunogenicity of HIV-1 CTL epitopes in this region. Several different patterns of cross-reactivity and selective recognition of wild-type and variant epitopes were found.
- LVGPTPVNv variant is detected due to appearence of I84V resistance mutation. Three patients receiving PIs had viral sequences obtained, and two had the I84V mutation. EliSpot reactivity to this epitope in either form was evident in these patients, showing drug resistnace can persist coincident with an active CTL response.

HXB2 Location Protease (76–84)
Author Location Protease (76–84)
Epitope `LVGPTPVNI`
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A2)
Country United States
Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords acute/early infection, optimal epitope
References Altfeld *et al.* 2005

- The most frequently targeted HLA-A2-restricted CD8+ T-cell epitopes in chronic infection were significantly less frequently recognized during primary infection. This epitope was only recognized during chronic infection.

HXB2 Location Protease (76–84)

Epitope LVGPTPVNI
Immunogen HIV-1 infection
Species (MHC) human (A2)
Country Canada
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords variant cross-recognition or cross-neutralization, characterizing CD8+ T cells, mimics
References Mason *et al.* 2005

- CTL responses against the human IP-30 signal peptide sequence LLDVPTAAV were shown to be elicited by stimulation of PBMCs from HIV-1 infected individuals with HIV protease peptide 76-84, LVGPTPVNI. In vitro stimulation with HIV PR 76-84 or the IP-30 signal peptide was shown to activate a comparable population of cross-reactive effector cells. None of the peptides activated CTL in non-HIV-infected individuals. IP-30 signal peptide was shown to have lower avidity T-cell interactions than the HIV peptide.
- As a control, responses to A2-restricted HIV epitopes ALVEICTEM, EELRQHLLRW, and LSPRTLNAW were shown not to give IP-30 responses.

HXB2 Location Protease (76–84)
Author Location Protease
Epitope LVGPTPVNI
Epitope name A2-LI9(Pro)
Immunogen HIV-1 infection
Species (MHC) human (A2)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

HXB2 Location Protease (76–84)
Author Location Pol (156–164)
Epitope LVGPTPVNI
Immunogen HIV-1 infection
Species (MHC) human (A2 supertype)
Keywords supertype, rate of progression
References Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind three of the five HLA-A2 supertypes alleles (A*0201, A*0202, A*0203, A*0206 and A*6802).

Author Location (C consensus)
Epitope LVGPTPVNII
Subtype C
Immunogen HIV-1 infection
Species (MHC) human (A*0205)
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, optimal epitope
References Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.

CTL CD8+

- LVGPTPVNII is an optimal epitope.

HXB2 Location Protease (77–85)
Author Location Protease (C-96BW15C05)
Epitope `IGPTPVNII`
Epitope name D
Subtype C
Immunogen vaccine
Vector/Type: DNA, alphavirus replicon *Strain:* C clade C-96BW04.09, C clade C-96BW15C05 *HIV component:* Gag, Gag-Pol, Pol
Species (MHC) mouse (H-2^d)
Assay type Flow cytometric T-cell cytokine assay
Keywords vaccine-induced epitopes, vaccine antigen design
References Megede *et al.* 2006

- HIV clade C gag, pol and fusion gagpol vaccines were compared in mice. Breadth of T cell responses was improved in mice immunized with gagpol fusion genes, compared to single antigen constructs. 5 new murine CD8+ T cell epitopes were mapped.
- This is a novel epitope.

HXB2 Location Protease (77–85)
Author Location Pol
Epitope `VGPTPVNII`
Epitope name V
Subtype B
Immunogen vaccine
Vector/Type: DNA with CMV promotor, modified vaccinia Ankara (MVA), DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade, B clade, C clade Du422, Other *HIV component:* Gag, Nef, RT
Species (MHC) mouse (H-2D^d)
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining, Other
Keywords subtype comparisons, vaccine-induced epitopes, variant cross-recognition or cross-neutralization, antagonism
References Larke *et al.* 2007

- Cross-clade vaccine recognition was studied using either single-, multi or several anatomically separated single-clade vaccines. Limited cross-clade response was seen with single-clade administrations. Multi-clade vaccines gave immune interference (antagonism and original antigenic sin), reducing CTL response. Simultaneously administered but anatomically separated vaccines from clades A, B, C decreased antagonism and increased immune responses.
- Clade-B vaccination induced recognition of index epitope VGPTPVNII and variant VGPTPiNII.

HXB2 Location Protease (79–89)
Author Location Protease
Epitope `PTPVNIIGRNL`
Subtype B, C
Immunogen HIV-1 infection
Species (MHC) human (B63)
Assay type CD8 T-cell Elispot - IFNγ
Keywords cross-presentation by different HLA, optimal epitope
References Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- Putative HLA-B63/57/58 epitope containing the B58 supertype binding motif. Significantly more often recognized by B63-positive subjects than by negative subjects, trend towards being more often recognized in those with B57/B58.

HXB2 Location Protease (80–89)
Author Location Pol
Epitope `TPVNIIGRNL`
Epitope name Pol1151
Subtype B
Immunogen HIV-1 infection, computer prediction
Species (MHC) human (B7)
Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords binding affinity, computational epitope prediction, HLA associated polymorphism
References De Groot *et al.* 2008

- 45 highly conserved, putative HLA-B7-restricted epitopes were identified with EpiMatrix and evaluated for HLA binding and ELISpot assays. 40 epitopes were functional and 18 of them are novel, 7 were not previously described as HLA-B7-restricted.
- Epitope TPVNIIGRNL elicits IFN-gamma ELISpot responses in 3/7 subjects; and bound HLA-B7 with low and high affinities in soluble and cell-based assays respectively. Previously published HLA restrictions of this epitope include B63, B57, B58 (LANL database).

Epitope `TPVNIIGRNML`
Epitope name TL11
Subtype C
Immunogen HIV-1 infection
Species (MHC) human
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Other
Keywords supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism
References Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Statistically significant associations between numbers of HLA-8101 expressing subjects and epitope TPVNIIGRNML were found.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope TL11 restriction.

HXB2 Location Protease (85–99)

Epitope `IGRNLLTQIGCTLNF`
Subtype B
Immunogen HIV-1 infection, vaccine
Vector/Type: DNA *Strain:* B clade *HIV component:* Gag *Adjuvant:* aluminum phosphate
Species (MHC) human
Country United States
Assay type CD8 T-cell Elispot - IFNγ, Other
References Balamurugan *et al.* 2008

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.
- CTL immune response to consensus sequence IGRNLLTQIGCTLNF was elicited in subject 00016. Consensus epitope of subjects was the same as Clade B consensus.

HXB2 Location Protease (91–99)
Author Location Pol (2529–)
Epitope `TQIGCTLNF`
Epitope name B*1501 TF9
Subtype B, C, CRF01_AE
Immunogen HIV-1 infection
Species (MHC) human (B*1501)
Country Australia
Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, HLA associated polymorphism
References Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore et al., Science 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- The mutational pattern in the third position in this epitope TQiGCTLNF, is correlated with the host carrying HLA B*1501.
- This epitope was experimentally tested using Interferon-g Elispot and functional avidity studies. For one of six patients tested, the form TQ(L)GCTLNF showed decreased functional avidity relative to TQiGCTLNF. In all other patients, the form TQ(L)GCTLNF had greater functional avidity than the form TQiGCTLNF.

HXB2 Location Protease (91–99)

CTL CD8+

Author Location Protease
Epitope TQIGCTLNF
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B*1503)
Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, rate of progression, immunodominance
References Frahm *et al.* 2006

- CTL responses restricted by HLA-B*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects inspite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominanat CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.
- TQIGCTLNF of clade B is a potential HLA-B*1503-restricted epitope, with epitope TQlGCTLNF found in clade C.

HXB2 Location Protease (91–99)
Author Location Protease (91–99 HXB2)
Epitope TQICGTLNF
Epitope name TF9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B62, Cw3)
Country Germany
Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, HLA associated polymorphism, drug resistance
References Mueller *et al.* 2007

- To assess HIV-1-specific CTL influence on development and patterns of drug resistance in protease (PR) 94 HLA-typed patients were analyzed. 10 new CTL epitopes were defined statistically and experimentally, and 26 correlations (positive and negative) between HLA class-I alleles and PR mutations - some leading to escape mutations - were detected, demonstrating that CTL epitopes can be predicted based on HLA-amino acid substitution associations.
- Some patient CTL escape mutations were detectable by other CTLs of the same patient. Correlations between resistance mutations, polymorphisms and specific PR inhibitors were not detected.
- HLA-B had the strongest impact on PR sequence change, though HLAs-A and -C also had some impact.
- The authors suggest that CTL escape is active in developing drug-resistance related polymorphisms as well as major and minor mutations in HIV-1 infected persons.
- HIV-1 subtype breakdown in this cohort was follows - 83/94 patients infected with subtype B virus, 3 with subtype C, 4 CRF01_AE, 1 CRF03_AB, 1 CRF15_01B and 2 subtype Ds.
- This newly defined epitope, TQICGTLNF, TF9, carries minor HLA-B62 and -Cw3-associated mutations at I93L, viz. TQlCGTLNF.

II-B-11 Protease-RT CTL/CD8+ epitopes

HXB2 Location Protease-RT (95–5)
Author Location Gag (175–184)
Epitope CTLNFPISPI
Immunogen HIV-1 infection
Species (MHC) human (A2 supertype)
Keywords supertype, rate of progression
References Propato *et al.* 2001

- The epitope starts in Protease and ends in RT.
- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind all five HLA-A2 supertypes alleles (A*0201, A*0202, A*0203, A*0206 and A*6802)

References Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope TLNFPISPI was predicted to be restricted by HLA A*0201 and A*0207.

Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A*02)
Country United States
Assay type Intracellular cytokine staining, Other
Keywords rate of progression, escape, immune evasion
References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, escape, HLA associated polymorphism
References Frater *et al.* 2007
- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than other HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by other, non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also had lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- Variants SsIETVPVKL and SPIkTVPVKL at positions 2 and 4 were the predominant polymorphisms found.

Species (MHC) human
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Other
Keywords supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism
References Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Statistically significant associations between numbers of HLA-8101 expressing subjects and epitope SPIETVPVKL were found.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope SL10 restriction.

Epitope IETVPVKL
Epitope name IL8
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B*40)
Country Australia, Canada, Germany, United States
Keywords HLA associated polymorphism
References Brumme *et al.* 2008a

- 98 newly infected patients were studied to track early host HLA and Gag/Pol/Nef epitope immune responses' association with viral evolution. Response hierarchies were the same as those for later infection, and 50% of the most rapidly substituting epitopes were restricted by protective HLA, e.g. Gag B*57-associated mutations which were the most rapidly reverting upon transmission to a non-B*57-host. While there are great differences in mutation rates and reversions across the HIV proteome, most early viral change is driven by immune pressure.
- HLA-driven epitope evolution was seen in 80% of published CTL epitopes.
- HLAs-B*40-associated substitutions within optimally defined epitope IETVPVKL are at positions E2 and K7, IeTVPVkL.

References Draenert *et al.* 2006

- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their seroconversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
- This epitope, IETVPVKL (IL8), restricted by HLA-B*4001, had variants IdTVPVKL and IETVPVrL arise.

Epitope name IL-8
Immunogen HIV-1 infection
Species (MHC) human (B40)
Keywords escape, TCR usage, immune evasion
References Yu *et al.* 2007b

- The dependence of TCR clonotype recruitment on genetic background was determined by studying monozygotic twins infected with the same HIV-1 strain. After an early, initial correlation in the magnitude, specificity and immunodominance of CTL response [Draenert et al. J. Exp. Med. 203:529-539(2006)], subsequent disease was mixed with respect to CTL epitopes' mutational escape. TCR alpha and beta chain repertoires were analyzed and it was found that their clonotypes in HIV-specific CTLs were broadly heterogeneous for both concordant and discordant epitope sequence evolution between the twins. Therefore initial TCR recruitment appears to be an entirely random process independent of genetic background of the infected individual.
- This epitope, IL8, showed discordant epitope evolution between the twins, and both alpha and beta TCR chains recruited were entirely different between them.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope GPKVKQWPL was predicted to be restricted by HLA B*0702, B*0801, B*3501, B8.

Keywords characterizing CD8+ T cells
References Streeck *et al.* 2008a

- T-cells were studied for exhaustion and dysfunction in chronic HIV infection. Polyfunctionality of CTL immune response to HIV-1 decreased with persistence of antigen presence over time in chronic infection. CTL exhaustion can thus be halted by reduction in viral antigen load - either by ART or through escape mutations.
- PD-1, marker for activation and apoptosis increases over time, but it decreases when epitope mutations develop. CD127 however, is not impacted by viral escape.
- 261 days after first testing, epitope GPKVKQWPL showed no variation in a treated patient. Previously published HLA-restriction for GL9 is HLA-B7.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords escape, variant cross-recognition or cross-neutralization, optimal epitope
References Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The GL9 variant GPrVKQWPL was essentially the only form of the epitope detected over a 5-year period in this person. Elispot reactions were roughly equivalent between the autologous form and the B clade consensus form, GPKVKQWPL. A single variant was observed in 1/8 clones at the 5-year time point, GPrVKQgPL.

CTL CD8+

References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- In one patient, initially the consensus sequence ALVEICTEM was not found. Instead the 35I variant ALiEICTEM was seen, followed by the emergence of the 35M variant, ALmEICTEM, and finally, emergence of the consensus B sequence, ALvEICTEM. Strongest immune responses were detected to the 35M variant and weaker responses to the 35I variant, while negligible responses were seen to the consensus, ALVEICTEM. This is an example of CTL-responses against variant epitopes causing virus evolution to the consensus B sequence. Other variants that emerged were ALtEICTEM, ALiEICTEt, ALiEICTdM, ALmkICTEM and ALmEICaEM.
- Responses to epitope ALVEICTEM were seen in early chronic infection. This was one of the epitopes targeted by broad HLA-A2-restricted CTL responses.

References Singh & Barry 2004

- When A*0201-C3H/J transgenic mice were immunized with plasmids encoding wild-type gag-pol, codon-optimized (CO) gag-pol, and an expression library vaccine expressing 16 fragments of gag-pol fused with ubiquitin for proteosome targeting (ELI), the ELI vaccine produced up to 10-fold higher CD8 T-cell responses than the other two vaccines. In contrast to the wt and CO vaccines, which tended to augment only immunodominant responses, boosting with the ELI vaccine resulted in many CD8 responses against variant epitopes from different HIV-1 clades, and against drug-resistant variants.

- Different variants of this epitope from different clades were tested. WT and CO vaccines produced low level CD8+ T-cell responses against the B clade form as well as against variants from other clades, but the ELI vaccine produced much more intense responses against the B clade and all variants tested, including after boosting. The variants were: clade A, alTDictem; clade C, atTAicEem; and clade D, alIeicSem.

Epitope `ALVEICTEM`
Epitope name A9M
Immunogen vaccine
Vector/Type: measles virus (MV) *Strain:* multiple epitope immunogen *HIV component:* gp140, gp140ΔV3
Species (MHC) transgenic mouse (A*0201)
Assay type Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords memory cells, vaccine antigen design, antibody generation, characterizing CD8+ T cells
References Lorin *et al.* 2005a

- A recombinant measles MVSchw virus expressing an HIV-1-derived polyepitope effectively primed HLA-A*0201-restricted CTL responses against multiple conserved HIV-1 epitopes in HLA-A*0201 transgenic mice. Also, a recombinant MVSchw virus expressing gp140 with deleted V1, V2, and V3 loops successfully induces neutralizing antibodies against HIV-1. A live attenuated measles vaccine could provide a safe and efficient pediatric vaccination vector for simultaneous vaccination against HIV and measles.

Immunogen HIV-1 infection
Species (MHC) human (A2)
Country Canada
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords mimics
References Mason *et al.* 2005

- CTL responses against the human IP-30 signal peptide sequence LLDVPTAAV were shown to be elicited by stimulation of PBMCs from HIV-1 infected individuals with HIV protease peptide 76-84, LVGPTPVNI. In vitro stimulation with HIV PR 76-84 or the IP-30 signal peptide was shown to activate a comparable population of cross-reactive effector cells. None of the peptides activated CTL in non-HIV-infected individuals. IP-30 signal peptide was shown to have lower avidity T-cell interactions than the HIV peptide.
- As a control, responses to A2-restricted HIV epitopes ALVEICTEM, EELRQHLLRW, and LSPRTLNAW were shown not to give IP-30 responses.

CTL CD8+

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Assay type CD8 T-cell Elispot - IFNγ
Keywords HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism
References Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A2 restricted epitope, ALVEICTEM was mutated to ALiEICTEM in the daughter D2 isolate.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

- CD8 T-cells targeting epitopes spanning drug resistance induced mutations were detected in 3/25 individuals harboring multidrug-resistant HIV-1. Novel CD8 T-cell responses were detected against epitopes with common protease inhibitor fitness mutations. T-cell immunity to drug-resistant variants was confirmed in SHIV-infected macaques, where CD8 and CD4 immune responses to RT and protease resistance mutations were elicited using peptide-based immunotherapy.
- The immune response to this peptide was cross-reactive for both the wild type and RT drug resistance mutation K65R, and NTPVFAIKK and ntpvfaikR stimulated CD8 T-cell responses with equal efficiency. The C-terminal R or K is required for a full response; NTPVFAIK stimulated a much weaker response.
- The 3 people that responded to the drug resistant forms of the virus were among those that had the highest levels of CD4 and CD8 T-cell responses, indicating that they were among the most immunocompetent.

References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, NTPVFAIKKK, is similar to human protein HERV, sequence SPwNTPVFvIKKK.

Epitope KLVDFRELNK
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A3)
References Samri *et al.* 2000

- This epitope contains the mutation L74V, a frequent mutation induced by nucleoside reverse transcriptase inhibitors.
- The wild-type, but not the mutated peptide, was recognized before and after zidovudine treatment in A3-restricted patients 252#0 and 252#4.
- Mutation L74V affects the p2 anchor position in RT epitopes and was predicted to reduce binding to A3 (http://bimas.dcrt.nih.gov/molbio/hla_bind)

Epitope KLVDFRELNK
Epitope name A3-KK10
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A3)
Donor MHC A3, B7, Cw7
Keywords dynamics, supervised treatment interruptions (STI), acute/early infection
References Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 0/14 HLA-A3 positive individuals had detectable A3-restricted responses to this epitope during acute infection, but only 5/15 of HLA-A3 epitopes tested were targeted during acute infection. 3/7 individuals began to have detectable responses to this epitope after STI.

Assay type Cytokine production, CD8 T-cell Elispot - IFNγ, Chromium-release assay, Other, HLA binding
Keywords vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism
References Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope TVLDVGDAY was predicted to be restricted by HLA B0702, B3501, B5102, B5103, B5301, B5401 and B5502 as well. B*1501, B*3501, B*5701, C*0304.

References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

Keywords assay standardization/improvement, optimal epitope
References Wang *et al.* 2007c

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A*11-restricted epitopes were recognized less frequently than other epitopes, and A*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, VLDVGDAYFSV, was detected within overlapping peptide KKKSVTVLDVGDAYFSV.

Author Location RT (267–277)
Epitope VLDVGDAYFSV
Immunogen in vitro stimulation or selection
Species (MHC) human (A*0201)
References van der Burg *et al.* 1996

- High dissociation rate, but immunogenic in primary CTL induction after repeated stimulations with peptide.
- CTL generated by *in vitro* stimulation of PBMC derived from uninfected individual.

HXB2 Location RT (108–118)
Author Location Pol
Epitope VLDVGDAYFSV
Epitope name V11V
Immunogen vaccine
Vector/Type: measles virus (MV) *Strain:* multiple epitope immunogen *HIV component:* gp140, gp140ΔV3
Species (MHC) transgenic mouse (A*0201)
Assay type Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords memory cells, vaccine antigen design, antibody generation, characterizing CD8+ T cells
References Lorin *et al.* 2005a

- A recombinant measles MVSchw virus expressing an HIV-1-derived polyepitope effectively primed HLA-A*0201-restricted CTL responses against multiple conserved HIV-1 epitopes in HLA-A*0201 transgenic mice. Also, a recombinant MVSchw virus expressing gp140 with deleted V1, V2, and V3 loops successfully induces neutralizing antibodies against HIV-1. A live attenuated measles vaccine could provide a safe and efficient pediatric vaccination vector for simultaneous vaccination against HIV and measles.

HXB2 Location RT (108–118)
Author Location RT (267–277)
Epitope VLDVGDAYFSV
Immunogen HIV-1 infection
Species (MHC) human (A2)
Keywords dendritic cells
References Kundu *et al.* 1998b

- Allogeneic dendritic cells (DCs) were obtained from HLA-identical siblings, pulsed with rgp160 MN or A2-restricted HIV-1 epitope peptides, and infused monthly into six HIV-infected patients.
- 1/6 showed increased env-specific CTL and increased lymphoproliferative responses, 2/6 showed increase only in proliferative responses, and 3/6 showed no change – pulsed DCs were well tolerated.
- VLDVGDAYFSV is a conserved HLA-A2 epitope included in this study – 4/6 patients had this sequence as their HIV direct sequence, but only one of these had a detectable CTL response – the other two had the sequences EEDVGDAYFSV and ELDVGDAYFSV and no detectable CTL response.

Assay type CD8 T-cell Elispot - IFNγ, Flow cytometric T-cell cytokine assay
Keywords rate of progression, escape
References Geels *et al.* 2003

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occured sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these eptiopes, but this increased over time.

Immunogen HIV-1 infection
Species (MHC) human (B*35)
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

References Brumme *et al.* 2008a

CTL CD8+

- 98 newly infected patients were studied to track early host HLA and Gag/Pol/Nef epitope immune responses' association with viral evolution. Response hierarchies were the same as those for later infection, and 50% of the most rapidly substituting epitopes were restricted by protective HLA, e.g. Gag B*57-associated mutations which were the most rapidly reverting upon transmission to a non-B*57-host. While there are great differences in mutation rates and reversions across the HIV proteome, most early viral change is driven by immune pressure.
- HLA-driven epitope evolution was seen in 80% of published CTL epitopes.
- HLAs-B*35-associated substitution within optimally defined epitope VPLDEDFRKY is at position D6, VPLDEdFRKY.

Keywords binding affinity, acute/early infection, early-expressed proteins
References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

References Yu *et al.* 2007b

- The dependence of TCR clonotype recruitment on genetic background was determined by studying monozygotic twins infected with the same HIV-1 strain. After an early, initial correlation in the magnitude, specificity and immunodominance of CTL response [Draenert et al. J. Exp. Med. 203:529-539(2006)], subsequent disease was mixed with respect to CTL epitopes' mutational escape. TCR alpha and beta chain repertoires were analyzed and it was found that their clonotypes in HIV-specific CTLs were broadly heterogeneous for both concordant and discordant epitope sequence evolution between the twins. Therefore initial TCR recruitment appears to be an entirely random process independent of genetic background of the infected individual.
- This epitope, YV9, showed discordant epitope evolution between the twins, and both alpha and beta TCR chains recruited were entirely different between them.

References Altfeld *et al.* 2001c

- HIV was scanned for all peptides which carried the A2-supermotif pattern conserved in more than 50% of B clade sequences – 233 peptides met this criteria, and 30 of these bound to HLA-A*0201 – 20/30 bound to at least 3/5 of HLA-A2 supertype alleles tested.
- Three additional previously described HLA-A2 epitopes were added to the set of 20, and 18/22 chronically infected HLA-A2 individuals had CTL that recognized at least one of the 23 peptides (median of 2 and maximum of 6), while 6/12 acute infected individuals recognized at least 1 (median of 1 and maximum of 2)
- 2/22 individuals with chronic HIV-1 infection recognized this epitope in ELISPOT.
- 0/12 acutely infected individuals recognized this epitope.
- YTAFTIPSI binds to five HLA-A2 supertype alleles: A*0201, A*0202,A*0203, A*0206 and A*6802 (highest affinity)

References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.

- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

References Streeck *et al.* 2007b

- A subject with acute and rapid disease progression to AIDS showed no neutralizing antibody activity and rapid decline in HIV-specific CTL response by 6 months post-infection. Virus from this rapid progressor was resistant to neutralization by plasma from a long-term progressor. Viral epitopes did not vary much. This suggests viral immune evasion in the absence of viral sequence variation.
- This epitope, YTAFTIPSI, elicited the dominant CTL response, detectable until 4 months post-infection. YI9 and its flanking sequences FRKYTAFTIPSINNE did not show any escape mutations.

Keywords immunodominance, escape, variant cross-recognition or cross-neutralization
References Draenert *et al.* 2006

- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their seroconversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
- This epitope, YTAFTIPSV (YV9) was restricted by HLA-A02. A variant that arose was YTAFTIPSi.

- T-cells were studied for exhaustion and dysfunction in chronic HIV infection. Polyfunctionality of CTL immune response to HIV-1 decreased with persistence of antigen presence over time in chronic infection. CTL exhaustion can thus be halted by reduction in viral antigen load - either by ART or through escape mutations.
- PD-1, marker for activation and apoptosis increases over time, but it decreases when epitope mutations develop. CD127 however, is not impacted by viral escape.
- One patient with epitope YTAFTIPSI maintained a mono- and dual-functional response profile.
- 141 days after first testing, epitope YTAFTIPSI showed no variation in a treated patient and after 182 days it varied to YTAFTIPSa/YTAFTIPSt/YTAFTIPSv in an untreated patient. Previously published HLA-restriction for YI9 is HLA-A2.

Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, escape, HLA associated polymorphism
References Frater *et al.* 2007

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than other HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by other, non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also had lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- TAFTIPSI escapes very soon after seroconversion to the variant TAFTIPSt with change at its carboxyl terminus, position 8, which has been identified by phylogenetic analysis to be under strong positive selection pressure. It was present in 7/8 of HLA-matched patients and 21/57 of HLA-unmatched patients.

Keywords epitope processing, escape
References Moore *et al.* 2002b
- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- TAFTIPSI was one of two epitopes characterized in detail. C-terminal I135x substitutions were associated with people who carried HLA-B5 – 39/40 (98%) of HLA-B*5101 individuals had substitutions in this position, while only 127/431 (29%) who did not have HLA-B*5101 did. The predominant substitution was kytaftipsT, and this mutation is predicted to abrogate binding to HLA-B*5101.

Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b
- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- Last position (8) of the epitope had potentially experienced positive selection. TAFTIPSt, TAFTIPSr and TAFTIPSv escape variants were found.

Assay type Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay, CTL suppression of replication
Keywords binding affinity, class I down-regulation by Nef, rate of progression
References Tomiyama *et al.* 2005
- HLA-B*5101 associated with slow progression to the disease state was studied as related to Nef-mediated HLA class I downregulation. It was shown that different CTLs have different ranges of ability to kill HIV-1 infected CD4+ T cells and suppress HIV-1 replication. This was found to be a function

CTL CD8+

of the specific HIV-1 epitope presented by the corresponding HLA allele to the CTL.
- Certain epitope recognising CTL clones or lines were therefore, capable of killing HIV-1 infected cells even in the presence of Nef-mediated MHC 1 downregulation, while other CTL clones recognising different epitopes were not so capable.
- There was no significant difference in cytokine production or cytokine producing cells between CTLs that were capable of killing CD4+ T-cells infected with HIV-1 and those CTLs that could not kill such HIV-1 infected cells.
- On the basis of studies involving binding abilities and cytolytic activities for four different epitopes that correlate with HLA-B*5101-restricted CTLs, it is suggested that the ability of CTLs to kill infected CD4+ T cells is due to the number of epitopes presented by the HLA on the surface of the CD4+ T cells rather than the ability of TCR to recognise the epitope.

References Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

References Casazza *et al.* 2005

- Evidence of continued viral evolution during HAART therapy despite low viral load was found in 1/5 patients studied. This epitope provided the best evidence for apparent immune escape during HAART.
- Prior to the initiation of therapy, taftipsT variant was found in 24/24 clones. At week 14 of therapy, this variant was completely replaced with taftipsI. By week 19, a complete replacement occurred again, this time to taftipsM. The change at nucleotide level suggests a stepwise progression from ACA to ATA to ATG.
- The taftipsT and taftipsM variants had lower avidity than the taftipsI variant, but this wasn't evident at saturating conditions; only careful titrations revealed the difference. HLA-B51 stabilization studies revealed the increased stabilization with the taftipsI form. Also, CD3 down-regulation was larger in response to taftipsI.
- The viral shift to the taftipsM variant during HAART was predicted to have minimal or undetectable effect on drug sensitivity.

Immunogen HIV-1 infection

Species (MHC) human (B51)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Assay type CD8 T-cell Elispot - IFNγ
Keywords supertype, cross-presentation by different HLA
References Frahm *et al.* 2007b

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- In addition to its known HLA association (B51), 2 additional HLAs (B35, B40) were statistically predicted to be associated with this epitope.

Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Flow cytometric T-cell cytokine assay
Keywords characterizing CD8+ T cells
References Streeck *et al.* 2008a

- T-cells were studied for exhaustion and dysfunction in chronic HIV infection. Polyfunctionality of CTL immune response to HIV-1 decreased with persistence of antigen presence over time in chronic infection. CTL exhaustion can thus be halted by reduction in viral antigen load - either by ART or through escape mutations.
- PD-1, marker for activation and apoptosis increases over time, but it decreases when epitope mutations develop. CD127 however, is not impacted by viral escape.
- Epitope TAFTIPSI varied to TAFTIPSa, TAFTIPSt and TAFTIPSv in an untreated patient. Previously published HLA-restriction for TI8 is HLA-B51.

Keywords TCR usage, characterizing CD8+ T cells
References Alter *et al.* 2008

- By studying HIV-1 dysregulation of CTLs at different infection stages induced by inhibitory KIRs (Killer Immunoglobulin-like receptors), it was determined that KIR surface expression on memory T cells correlates with HIV replication. It results in reduced activation, proliferation, cytokine secretion, and killing following TCR stimulation. Since non-TCR-dependent CTL stimulation was unaffected, TCR-mediated stimulation appears to be defective. KIR induced suppression of CTL function was found to be KIR-ligand-independent.
- TI8-specific, HLA-B51-restricted CTL were used for an HIV inhibition assay.

References Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, YFPDWQDYT, was found to be 0.002/day (optimistic escape rate = 0.012), with SE of 0.001.
- In the subject studied, the monotonic outgrowth of a I290T mutation in Pol was observed over a period of 817 days.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- NNETPGiRY, NsETPGVRY, NNEiPGVRY, NNEiPGiRY, NNgTPGVRY and NNEvPGiRY escape variants were found.

Assay type T-cell Elispot
Keywords supervised treatment interruptions (STI), immunodominance, early treatment
References Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 19% of the study subjects, and it was one of the 25 most frequently recognized peptides.

Epitope SPAIFQSSM
Epitope name B7-SM9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B7)
Donor MHC A3, B7, Cw7
Keywords dynamics, supervised treatment interruptions (STI), acute/early infection
References Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 1/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 3/4 individuals had detectable responses to this epitope after STI.

Immunogen HIV-1 infection
Species (MHC) human (B7)
Country United States
Assay type CD8 T-cell Elispot - IFNγ
Keywords assay standardization/improvement, epitope processing
References Draenert *et al.* 2004a

- 96% of optimally defined epitopes have one of only nine amino acids serving as the C-terminal anchor position. Seven amino acids are never found in this position and four are only present in 4% of cases. CD8 T-cell response to an epitope is shown to be best detected when the epitope is situated at the C-terminal end of a longer peptide, and authors suggest that Elispot reagents would be better designed if peptides ended on known C-terminal anchors.
- SPAIFQSSM is suggested to be the optimal epitope instead of SPAIFQSSMT.

HXB2 Location RT (156–164)
Author Location (B consensus)
Epitope SPAIFQSSM
Epitope name SM9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B7)
Donor MHC A03, B07, Cw7
Assay type Cytokine production, Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords assay standardization/improvement, memory cells, characterizing CD8+ T cells
References Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

Immunogen HIV-1 infection
Species (MHC) human (B7)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Immunogen HIV-1 infection
Species (MHC) human
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Other
Keywords supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism
References Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction
- Statistically significant associations between numbers of HLA-0702 and -B8101 expressing subjects and epitope SPAIFQSSM were found.
- Only B*0702 was found to be associated with polymorphism in SM9.

Immunogen HIV-1 infection
Species (MHC) human
Country Sweden
Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, computational epitope prediction, variant cross-recognition or cross-neutralization
References Pérez *et al.* 2008

- Bioinformatic prediction using NetCTL 1.0, Episelect and NetMHCpan generated 184 CTL epitopes from Gag, Pol, Nef, Env and Tat in HIV subtypes A, B, C, D and CRF01_AE, restricted by MHC A1, A2, A3, A24, B7, B44 and B58. 45 of the 114 epitopes recognized experimentally in subjects were novel, and an elite subgroup comprising 21 epitopes were recognized by at least 13% of patients tested.

- Response magnitude was high—Gag and Nef, Env, Tat in descending order). While Gag, Pol, Env and Nef were highly immunocgenic, only 38% Tat epitopes elicited a response.
- 4 patterns of cross-subtype recognition found were (a) conserved epitopes recognized by patients infected with several HIV subtypes (b) infrequently found reference epitopes recognized by patients infected with several HIV subtypes (c) epitopes more prevalent in certain subtypes recognized by patients infected with several subtypes (d) rarely, subtype-specific epitopes unable to elicit cross-clade recognition
- Broadly immunogenic epitope SPAIFQSSM, had subtype variants that were recognized by less than half its patient responders. This epitope is predicted to be restricted by HLA supertype B7.

Immunogen HIV-1 infection
Species (MHC) human (B7)
Keywords epitope processing, escape
References Moore *et al.* 2002b

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- HLA-B7+ individuals with a S162x (18/33) substitution had higher viral loads than those that did not, suggesting escape was associated with diminished immune control of viremia.

Epitope name AK9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A*03, A*11)
Country Australia, Canada, Germany, United States
Keywords escape, HLA associated polymorphism
References Brumme *et al.* 2008a

- 98 newly infected patients were studied to track early host HLA and Gag/Pol/Nef epitope immune responses' association with viral evolution. Response hierarchies were the same as those for later infection, and 50% of the most rapidly substituting epitopes were restricted by protective HLA, e.g. Gag B*57-associated mutations which were the most rapidly reverting upon transmission to a non-B*57-host. While there are great differences in mutation rates and reversions across the HIV proteome, most early viral change is driven by immune pressure.
- HLA-driven epitope evolution was seen in 80% of published CTL epitopes.
- HLAs-A*03 and A*11-associated substitution within optimally defined epitope AIFQSSMTK is at position K9, AIFQSSMTk. AK9 has a low recognition frequency and very low number of escapes.

Keywords subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance
References Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFNgamma Elispot assays after vaccination of 5 macaques. The response to the Mamu A*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

References Sriwanthana *et al.* 2001

- This was a study of HIV-1 exposed persistently seronegative (HEPS) female sex workers in Chiang Mai, northern Thailand.
- HLA-A11 is very common in this population, and was enriched among the HEPS sexworkers – weak CTL responses were detected in 4/7 HEPS women, and CTL responses were found in 8/8 HIV+ controls, and 0/9 HIV- women that were not exposed.
- This epitope was weakly reactive in the HEPS study subject 128 who was HLA A11/A33.
- This epitope was strongly reactive in HIV+ study subjects 053 and 184 who carried HLA-A11.

Immunogen HIV-1 infection
Species (MHC) human (A11)
Keywords subtype comparisons
References Bond *et al.* 2001

- HLA-A11 CRF01 (called subtype E in Bond *et al.*) epitopes were identified that stimulated CTL from HIV+ female sex workers (FSW) from Northern Thailand, of whom more than half were HLA-A11 positive.
- 77 possible HLA-A11 epitopes were first defined using EpiMatrix, these were screened for binding to A11 finding and 26 bound, and 12 of these were epitopes for CTL responses from 8 HLA-A11 positive FSWs, six were novel, six were previously identified.
- This epitope was predicted by the EpiMatrix method to be likely to bind to A11, and it served as an epitope in the FSWs, it was one of the six A11 epitopes that had been previously defined.
- 6/8 tested FSWs recognized this epitope.
- An HLA-A11 tetramer was made for this epitope, which was recognized by two subjects – and both subjects had expanded tetramer staining T-cell populations after *in vitro* stimulation.
- This epitope was highly conserved in other subtypes, and exact matches were common.

Epitope AIFQSSMTK
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A11)
Keywords epitope processing, escape
References Moore *et al.* 2002b

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- HLA-A11+ individuals with a K166x (4/19) substitution had higher viral loads than those that did not, suggesting escape was associated with diminished immune control of viremia.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords escape, optimal epitope
References Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The AK9 variant AIFQSSMTr was essentially the only form of the epitope detected over a 5-year period in this person. Elispot reactions indicated the T-cell clones only recognized the autologous form, not the B clade consensus, AIFQSSMTK. Two rare variants were observed at the 5-year time point, tIFQSSMTr and AIFQSSMar.

Subtype A, B, C
Immunogen vaccine
Vector/Type: DNA with CMV promotor, modified vaccinia Ankara (MVA), DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade, B clade, C clade Du422, Other *HIV component:* Gag, Nef, RT
Species (MHC) mouse (H-$2K^d$)
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining, Other
Keywords subtype comparisons, vaccine-induced epitopes, variant cross-recognition or cross-neutralization, antagonism
References Larke *et al.* 2007

- Cross-clade vaccine recognition was studied using either single-, multi or several anatomically separated single-clade vaccines. Limited cross-clade response was seen with single-clade administrations. Multi-clade vaccines gave immune interference (antagonism and original antigenic sin), reducing CTL response. Simultaneously administered but anatomically separated vaccines from clades A, B, C decreased antagonism and increased immune responses.
- After immunization with A-clade vaccine, index epitope P, IFQSSMTKI, and variant IFQaSMTKI were recognized. Variant IFQcSMTKI was not recognized.

Epitope MTKILEPFR
Epitope name MR9
Immunogen
Species (MHC) human (A*0301)
References Zimbwa *et al.* 2007

- E169D is a processing mutation for HLA-B*0702 restricted SPAIFQSSM (SM9) as well as an epitope variation for HLA-A*0301 restricted MTKILEPFR (MR9).
- CTL recognition of MR9 was detected 5 days post-infection with wild type (169E) HIV-1, but not with mutant 169D virus bearing eptiope MTKILdPFR.
- Binding assays found a 44% reduction in binding to HLA-A*0301 by the variant epitope MTKILdPFR.
- Mutation 169D lies within MR9. In vitro proteasome processing assays showed that both wild type or variant 27-mer synthetic peptide QGWKGSPAIFQSSMTKILE(d)PFRKQNPD released appropriate MR9-intermediate peptides within 6 h.

HXB2 Location RT (164–172)
Author Location Pol (343–351)
Epitope MTKILEPFR
Immunogen HIV-1 infection
Species (MHC) human (A3 supertype)
Keywords supertype, rate of progression
References Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind 4/5 HLA-A3 supertype alleles (A*0301, A*1101, A*3101, A*3301 and A*6801).

HXB2 Location RT (164–172)

Epitope MTKILEPFR
Subtype B
Immunogen HIV-1 infection, peptide-HLA interaction
Species (MHC) human
Assay type CD8 T-cell Elispot - IFNγ
Keywords immunodominance
References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.

CTL CD8+

- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, MTKILEPFR, is similar to human protein Piwi-like 2, sequence MTKILEPc and human protein SON DNA Binding protein, sequence sMTKILdsF.

HXB2 Location RT (173–181)

Epitope KQNPDIVIY
Epitope name KY9 (RT-53)
Immunogen HIV-1 infection
Species (MHC) human (A*3002)
References Goulder *et al.* 2001a

- HLA-A*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.
- A rapid method was developed combining ELISPOT with intracellular IFN-γ staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.
- Two individuals were studied: Subject 199 (HLA A*0201/*3002 B*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A*3002/ B53/*5801 Cw4/7) an African-Caribbean.
- In both HLA-A*3002 individuals the response to RSLYNTVATLY was dominant.
- In subject 199 four additional A*3002 epitopes were identified.
- Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41)

HXB2 Location RT (173–181)

Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Keywords HLA associated polymorphism
References Brumme *et al.* 2008a

- 98 newly infected patients were studied to track early host HLA and Gag/Pol/Nef epitope immune responses' association with viral evolution. Response hierarchies were the same as those for later infection, and 50% of the most rapidly substituting epitopes were restricted by protective HLA, e.g. Gag B*57-associated mutations which were the most rapidly reverting upon transmission to a non-B*57-host. While there are great differences in mutation rates and reversions across the HIV proteome, most early viral change is driven by immune pressure.
- HLA-driven epitope evolution was seen in 80% of published CTL epitopes.
- HLAs-B*35-associated substitution within optimally defined epitope NPDIVIYQY is at position D3, NPdIVIYQY.

Keywords epitope processing, escape
References Moore *et al.* 2002b

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- NPDIVIYQY was one of two epitopes characterized in detail. D177x substitutions are know to specifically abrogate binding to HLA-B*3501, and not other B*35 subtypes. D177x substitutions were associated with people who carried HLA-B*3501 and not other B*35 subtypes; considering high resolution typing generally strengthened the B*35 associations.

Keywords binding affinity, acute/early infection, early-expressed proteins
References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ INF-γ T-cell responses in 21 men within 15-92days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-γ secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

- This study examines CTL responses in HIV exposed, persistently seronegative individuals, HEPS, who eventually seroconverted – 11/114 HEPS Nairobi sex workers eventually seroconverted, and for six of these HIV CTL reactive epitopes had been defined while seronegative.
- HPDIVIYQY or NPDIVIYQY was recognized in 1 of the 6 women (ML857), and the response was present in the last available sample prior to seroconversion, 7 months.
- 20/20 sequences of the infecting strain had three substitutions in this epitope, all 20 were NpQiIiyqy, and this form was not recognized by CTL from ML 857 – this was the only case in the study where a virus carrying an unrecognized form of the epitope broke through.
- The epidemiological factor associated with seroconversion was stopping sex work. HIV-specific CTL activity declined when HEPS sex workers stopped working for a period or retired.
- NPDIVIYQY was recognized by 1/22 HEPS control sex workers, ML887.

HXB2 Location RT (175–183)
Author Location RT (175–183 SF2)
Epitope `NPDIVIYQY`
Immunogen HIV-1 infection
Species (MHC) human (B35)
Keywords HAART, ART, acute/early infection
References Altfeld *et al.* 2001b

- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.

- The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
- Previously described and newly defined optimal epitopes were tested for CTL response.
- Number of HLA-B35+ individuals that had a CTL response to this epitope broken down by group: 1/2 group 1, 0/2 group 2, and 1/1 group 3.

Epitope HPDIVIYQY
Immunogen HIV-1 infection, HIV-1 exposed seronegative
Species (MHC) human (B35)
Keywords HIV exposed persistently seronegative (HEPS), immunodominance
References Kaul *et al.* 2001a

- Variants (H/N)PDIVIYQY are specific for the A/B clades.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-B35 women, 2/3 HEPS and 1/4 HIV-1 infected women recognized this epitope.
- The dominant response to this HLA allele was to this epitope in only one of the 2/3 HEPS cases, and was not to this epitope in the one responsive HIV-1 infected women.
- Subject ML 857 shifted from a A*6802 DTVLEDINL and B35 (H/N)PDIVIYQY response prior to seroconversion to a B35 PPIPVGDIY and B35 VPLRPMTY response post-seroconversion and the loss of the pre-seroconversion response was not due to sequence variation within these epitopes.

Assay type Intracellular cytokine staining, Other
Keywords rate of progression, escape, immune evasion
References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

Epitope `VIYQYMDDL`
Immunogen HIV-1 infection
Species (MHC) human (A*0201)
Keywords epitope processing, immunodominance, escape
References Sewell *et al.* 1999

- Proteasome regulation influences epitope processing and could influence patterns of immunodominance.
- The proteasome is inhibited by lactacystin treatment, and gamma IFN induces expression of proteasome subunits, LMP2 and LMP7, which combine with the proteasome to create an immunoproteasome.
- IFN-gamma induction of the immunoproteasome and lactacystin inhibition increases the presentation of the A*0201 VIYQYMDDL epitope, but decreases the presentation of the A*0201 ILKEPVHGV epitope, which is immunodominant within pol proteins, showing the two epitopes are processed by different pathways.
- ILKEPVHGV seems to be processed by the classical proteasome pathway, while VIYQYMDDL appears to be destroyed by this pathway.
- This epitope contains the catalytic site (YMDD) of RT, a conserved sequence in HIV-1 which restricts escape mutants.

- Only 20% of CD8+ T-cells produce IFN-gamma and granzyme B simultaneously (Tc1a). Two additional subpopulations of HIV specific CD8 cells are found, each one constituting 30-40% of the CD8 cell pool. One of these (Tc1b) secretes IFN-gamma only, and the other one (Tc1c) secretes GzB only.
- One of seven patients responded to this peptide with GzB producing cells, while none of the patients responded with IFN-gamma producing cells.

Epitope VIYQYMDDL
Immunogen HIV-1 infection
Species (MHC) human (A*0201)
Assay type Cytokine production, CD8 T-cell Elispot - IFNγ, Chromium-release assay, Other, HLA binding
Keywords vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism
References Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope VIYQYMDDL was predicted to be restricted by HLA A*0201, A*0205, A*0207, A*0214.

Assay type CD8 T-cell Elispot - IFNγ
Keywords HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism
References Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than interperson sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A2/A*0201 restricted epitope, VIYQYMDDL was mutated to cIYQYMDDL in the daughter D2 isolate.

References Bolesta *et al.* 2005

- Immunization of transgenic mice with a codon-optimized hGagp17p24-Polp51 DNA plasmid, consisting of clusters of highly conserved CTL epitopes presented by multiple MHC class I alleles, induced 2- to 5-fold higher CD8+ T-cell responses than the corresponding full-length proteins. The modified proteins had the ribosomal frameshift deleted, as well as the potentially immunosuppressive p15, and protease and integrase. This correlated with higher protection against challenge with Gag and Pol expressing recombinant vaccinia virus. Mice immunized with the hGagp17p24-Polp51 also showed an elevated level of type 1 cytokine production as well as an increased titer of p24- and RT-specific IgG2 antibody responses.
- This was 1 of 4 A2 gag/pol epitopes tested. Transgenic mice immunized with the deleted construct induced more potent EliSpot reactions to this epitope than those immunized with full length Gag/Pol.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- Two patients developed responses to epitope YQYMDDLYV during primary infection and in early chronic infection.

Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Country Barbados, Haiti, United States
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining
Keywords binding affinity, immunodominance
References Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This overlapping peptide, KIEELRQHLLRWGFTTPDK, was differentially targeted across ethnic groups and had an overall frequency of recognition of 13.3% - 5.1% AA, 23.1% C, 25%

H, 0% WI (P value = 0.0018). HLA-B44 was the most commonly present HLA allele among individuals with responses to this peptide.

Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining
Keywords immunodominance, escape, variant cross-recognition or cross-neutralization
References Draenert *et al.* 2006

- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their seroconversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
- This epitope, IEELRQHLL (IL9) restricted by HLA-B*4001, was one of two immunodominant responses. Variants that arose were vEELReHLL and IEELReHLL.

Epitope IEELRQHLL
Epitope name B40-IL9(RT)
Immunogen HIV-1 infection
Species (MHC) human (B40)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Epitope IEELRQHLL
Epitope name IL-9
Immunogen HIV-1 infection
Species (MHC) human (B40)
Keywords escape, TCR usage, immune evasion
References Yu *et al.* 2007b

- The dependence of TCR clonotype recruitment on genetic background was determined by studying monozygotic twins infected with the same HIV-1 strain. After an early, initial correlation in the magnitude, specificity and immunodominance of CTL response [Draenert et al. J. Exp. Med. 203:529-539(2006)], subsequent disease was mixed with respect to CTL epitopes' mutational escape. TCR alpha and beta chain repertoires were analyzed and it was found that their clonotypes in HIV-specific CTLs were broadly heterogeneous for both concordant and discordant epitope sequence evolution between the twins. Therefore initial TCR recruitment appears to be an entirely random process independent of genetic background of the infected individual.
- This epitope, IL9, showed concordant epitope evolution between the twins, but both alpha and beta TCR chains recruited were entirely different between them.

Assay type CD8 T-cell Elispot - IFNγ
Keywords HAART, ART, supervised treatment interruptions (STI), early treatment
References Montefiori *et al.* 2003

- HIV-1 + patient AC10 underwent early HAART treatment, which was discontinued 1.5 years later. At this timepoint potent NAb responses against autologous virus were detected. Treatment interruption initially induced weak CD8+ responses directed against 5 epitopes. By days 873d and 923d the CTL response had broadened to target 22 epitopes; of these six were fully characterized. Eventually the virus escaped the NAb response, but escape was not accompanied by a rise in viral load, and the authors suggest the virus was contained by the CTL response.

Epitope EELRQHLLR
Immunogen HIV-1 infection
Species (MHC) human (B44)
Donor MHC A*3101, A68, B*4403, B51
Keywords HAART, ART, supervised treatment interruptions (STI)
References Arnedo-Valero *et al.* 2004

- T cell immune responses following STI were monitored in two chronically HIV-1 infected partners (A and B) who had contracted HIV-1 during 1992. Both were heterozygous for the CCR5 delta32, and had different HLAs and treatment histories. STI induced strong transitory CD4+ and CD8+ T cell responses in both patients. Patient A displayed broad CD8+ T cell responses directed against Env, Pol, Gag, and Nef HIV-1 antigens. CTL responses in patient B were mainly directed against two epitopes: Gag(p24)NANPDSKTI and Pol(RT)EELRQHLLRW.
- Despite the host differences, both patients had similar dynamics of vial evolution and CD4+ T-cells, suggesting that good immune reponses to STI may be more related to the virus than host characteristics in these cases.

References Arnedo-Valero *et al.* 2004

- T cell immune responses following STI were monitored in two chronically HIV-1 infected partners (A and B) who had contracted HIV-1 during 1992. STI induced strong transitory CD4+ and CD8+ T cell responses in both patients. The viruses remained very closely related over 10 years, despite the two individuals having different HLA types; the authors suggest the maintained similarity does not support a strong role for HLA driven HIV diversity as has been claimed in Moore et al. (Science 2002).

CTL CD8+

- During the second treatment stop, patient A developed a strong proliferative response to p24, and multiple strong CD8+ T cell repsonses to Env, Pol, Gag and Nef. This patient was able to control viral load for two years follow up without therapy. Patient B developed a very weak CD4+ T cell response against p24 during breaks in therapy, and had CD8+ responses to two epitopes. Patient A: A01, A32, B*1410, B15; Patient B: A*3101, A68, B*4403, B51.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Position 8 in the epitope had potentially experienced positive selection. ELRQHLLkW escape variant was found.

References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

References Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- Responses to this peptide were detected in 16% of the study subjects, and it was one of the 25 most frequently recognized peptides.

References Brumme *et al.* 2008a

- 98 newly infected patients were studied to track early host HLA and Gag/Pol/Nef epitope immune responses' association with viral evolution. Response hierarchies were the same as those for later infection, and 50% of the most rapidly substituting epitopes were restricted by protective HLA, e.g. Gag B*57-associated mutations which were the most rapidly reverting upon transmission to a non-B*57-host. While there are great differences in mutation rates and reversions across the HIV proteome, most early viral change is driven by immune pressure.
- HLA-driven epitope evolution was seen in 80% of published CTL epitopes.

CTL CD8+

- Escape (and reversion) rates for B*57-restricted epitopes were highest for Gag-TW10 (TSTLQEQIGW) > RT-IW9 (IVLPEKDSW) > Nef-YY9 (YTPGPGIRY) > Nef-HW9 (HTQGYFPDW) > Gag-IW9 (ISPRTLNAW) > Gag-KF11 (KAFSPEVIPMF) .
- HLAs-B*57-associated substitutions within optimally defined epitope IVLPEKDSW are at positions V2 and E4, IvLPeKDSW. IW9 was the 7th most rapidly escaping epitope.

Keywords acute/early infection, early-expressed proteins, kinetics
References van Baalen *et al.* 2002

- Tat, Rev and Nef are the first HIV proteins expressed upon acute infection of T-cells (< 6 hours), and RT is not expressed until after 24 hours. The B14-restricted Rev-SAEPVPLQL specific CD8 T-cell clone TCC108, and the B57-restricted RT-IVLPEKDSW specific CD8 T-cell clone TCL1C11 were co-incubated with CD4+ cultures innoculated with HIV-1 at low MOI. Co-incubation with the Rev-specific CTL resulted in two logs less HIV-1 production in ten days of culture. When the RT epitope was cloned into the Nef gene of the infecting strain, another early expressed protein, it proved as effective as the Rev epitope at inhibiting viral production. A mathematical model of CTL-target interactions suggest early proteins are important for vaccine design.

References Streeck *et al.* 2007a

- To characterize HIV-1 proteome areas that are targeted in early, effective CTL responses, two cohorts were studied. Responses in early infection were against fewer epitopes and of lower magnitude than during chronic infection. While no region of the proteome was favored, Nef was the predominant target based on length of proteins.
- When based on the expression of protective versus nonprotective HLA I alleles, it was found that HLA-B27 and -57 possessing slow progressors to disease directed the majority of their responses to Gag in early infection, as opposed to those with HLA-B*3501 or B*3502, i.e. rapid progressors to AIDS, who had negligible responses to Gag. As compared with HLA-B57-/B27- subjects and HLA-B35 subjects, HLA-B57+/27+ subjects responded most to the p24 component of Gag. By using overlapping peptides within Gag p24, two were picked as being consistently targeted, and both contained previously described epitopes TSTLQEQIGW and KRWIILGLNK.
- IVLPEKDSW, i.e. epitope IW9 of RT protein was targeted in 62% of B57+ non-progressors to disease.

Epitope name LY12
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B62)
Donor MHC A*01, A*11, B*08, B*15, Cw*04, Cw*07
Country United States
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords escape, characterizing CD8+ T cells, optimal epitope
References Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The autologous form of the epitope, LVGKLNWASQIY, matched the B consensus throughout the 5-year period of study, with 1 rare variant at the first time point: LVGKLNWASQIh.

Epitope `KLNWASQIY`
Epitope name KY9 (RT-35)
Immunogen HIV-1 infection
Species (MHC) human (A*3002)
References Goulder *et al.* 2001a

- HLA-A*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.
- A rapid method was developed combining ELISPOT with intracellular IFN-γ staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.
- Two individuals were studied: Subject 199 (HLA A*0201/*3002 B*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A*3002/ B53/*5801 Cw4/7) an African-Caribbean.

- In both HLA-A*3002 individuals the response to RSLYNTVATLY was dominant.
- In subject 199 four additional A*3002 epitopes were identified.
- Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41)

Keywords HAART, ART, supervised treatment interruptions (STI)
References Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (`http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html`) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient D displayed the greatest response to B27-KK10 (p24), and also responded to A30-RY11(p17), A32-PW10(RT), A30-KY11(RT), A32-RW10(gp120), and B18-YY9(Nef).

CTL CD8+

Country China
Assay type CD8 T-cell Elispot - IFNγ
References Zhai *et al.* 2008

- 49 ART-naive chronically HIV-1 infected Chinese subjects' CTLs were tested with 413 OLPs in IFN-gamma assays, determining optimal epitopes specific for Chinese Clade B HIV-1 sequences.
- An inverse correlation was found between CTL response and viral load.
- Targeted peptides have lower entropy than peptides that are not CTL targeted. This correlation is independent of HLA-restriction.
- Previously described HLA-A30-restricted epitope KLNWASQIY elicited an immune response in Chinese HIV-1 positive subjects as peptide NDIQKLVGKLNWASQIYA but not as peptide KLNWASQIYAGIKVKQL.
- 1 of the 15 HLA-A30 carriers responded to KLNWASQIY-containing peptide #201 with average magnitude of CTL response of 40 SFC/million PBMC. Although the second tested peptide #202 contains the exact sequence of a previously described HLA-A30 optimal epitope, KLNWASQIY, none of the 15 HLA-A30 carriers responded to it (author communication and Fig.1).

Assay type CD8 T-cell Elispot - IFNγ, Other
References Balamurugan *et al.* 2008

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.
- CTL immune response to consensus sequence WASQIYAGIKVKQLC was elicited in subject 00015. Consensus epitope of subjects was the same as Clade B consensus.

Many polymorphisms were associated with multiple HLA allele classes. 12% associations were negative: association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles accounted for 50% of associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes.
- YPGIKVRQL was a previously defined B*4201 presented epitope that encompassed an B*42 associated polymorphism, YpGIKVRQL,in the second position. This epitope was found embedded in a previously determined immunoreactive region.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords rate of progression
References Gray *et al.* 2009

- 47 HIV-1 subtype C infected patients were followed longitudinally to determine whether there was a relation between magnitude and breadth of CTL responses in primary, acute infection (measured by IFN-gamma ELISpot) and disease progression (measured as viral load at 12 months). CTL responses to Nef were dominant (targeting 6 epitopic regions), followed by responses to Gag, Pol, Rev, Vpr, Env, Vpu, Vif and finally Tat.
- Known epitope YPGIKVRQL is HLA-B*4201-restricted. Response to a peptide containing this epitope was detected in a rapid progressor 12 weeks post-infection.

Epitope name YL9 ?
Immunogen HIV-1 infection
Species (MHC) human (B42)
Country United States, South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding
Keywords memory cells
References Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

Country South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Other
Keywords supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism
References Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Statistically significant associations between numbers of HLA-4201 expressing subjects and epitope YPGIKVRQL were found.

CTL CD8+

- A strong association between B*4201 and variation in epitope YL9 was found.

Keywords HLA associated polymorphism
References Rousseau *et al.* 2008

- 3 phylogenetic correction methods—MLL (maximum likelihood character state analysis followed by likelihood ratio test), MLF (maximum likelihood character state analysis followed by Fisher test), and parsimony character state analysis were used to identify points in the HIV-1 subtype C proteome that conferred susceptibility or resistance to CTLs. Associations of HLA-epitope combinations that were inferred to be susceptible or resistant were organized into immunological sets that would help identify the best residues and genes as candidates for vaccines. While all proteins were interrogated, Gag, Pol, Env and Nef were focused upon. Amino acid changes were evaluated for association with plasma viral load.
- Proteome maps may be seen at `http://www.hiv.lanl.gov/content/immunology/hlatem/study5/index.html` with information showing single or multiple sites involving escape and reversion.
- HLA- B and -C alleles associated more with aa changes than HLA-A, suggesting that the former two are more important in driving viral evolution.
- The ratio of susceptible to resistant residues in HIV proteins was in descending order, Vpr>Gag>Rev>Pol>Nef>Vif>Tat>Env>Vpu, showing that epitopes from the earlier proteins are more conserved owing to viral fitness cost upon mutation.
- This Pol HLA-B*42-restricted epitope, YPGIKVRQL, lies within a set of 6 immunological associations, experiencing conflicting selective pressures.

Assay type Cytokine production, Tetramer binding, Chromium-release assay
Keywords binding affinity, kinetics, TCR usage, characterizing CD8+ T cells, immune dysfunction
References Ueno *et al.* 2004b

- Two different clonotypes of CD8+ T-cells with specificity for this epitope were isolated from a chronic HIV+ patient. The clonotype with the relatively high affinity TCR had no cytolytic activity, cytokine production or proliferation in response to HIV-infected cells, while the moderate affinity clonotype had strong reactions. More than 3-fold increased duration in tetramer 1/2 life was observed with the defective clonotype. The TCRs from the two clonotypes preserved the phenotype when transduced into primary CD8+ T cells, suggesting the TCR with higher affinity was directly associated with impaired T-cell reactivity of the cells.
- The high affinity impared TCR was Valpha1.1/Vbeta13.3, the moderate affinity active TCR was Valpha12.1/Vbeta5.6.

Keywords rate of progression, immunodominance, escape
References Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses,and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant eptiopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- The IPL epitope was found to be under positive selection for escape mutations and it was replaced by first variant between days 297 and 369, ipltGeael. This new variant was subsequently replaced by 2 further variants, that were even more resistent to CD8+ T cell recognition between days 369 and 635, ipltAeael and ipltVeael.

References Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This overlapping peptide, ASRELERFAVNPGLL, was differentially targeted across ethnic groups and had an overall frequency of recognition of 13.3% - 6.8% AA, 26.9% C, 20.5% H, 0% WI (P value = 0.0028). HLA-A2 was the most commonly present HLA allele among individuals with responses to this peptide.

References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- Responses to epitope IV9 were seen in early chronic infection.

Author Location RT (309–317)
Epitope ILKEPVHGV
Epitope name IV9
Immunogen HIV-1 infection
Species (MHC) human (A*02)
Assay type CTL suppression of replication
Keywords class I down-regulation by Nef
References Adnan *et al.* 2006

- The impact of Nef on antiviral activity was studied. CTL-targeting epitopes were susceptible to the effects of Nef, both in late (Gag, RT, Env) and in early proteins (Rev, Nef), although to a lesser degree in early proteins. HLA-C-restricted CTLs (unlike HLA-A and HLA-B) were unaffected by Nef both in early (Nef) and late (Env) proteins.
- Late protein RT epitope ILKEPVHGV-recognizing CTLs were affected by Nef.

Epitope ILKEPVHGV
Immunogen HIV-1 infection
Species (MHC) human (A*0201)
Keywords acute/early infection
References Wilson *et al.* 2000a

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and a close temporal relationship between the number of circulating HIV-specific T cells and viral load.
- All three patients were B*2705, with HLA alleles: A1, A30/31, B*2705, B35; A1, A*0301, B7, B2705; and A*0201, A*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B*2705 epitope KRWIILGGLNK.
- The subject with A*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A*301-RLRPGGKKK, A*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A*0301, B7, B*2705.
- No acute response was detected to the following epitopes: A*201-ILKEPVHGV, A*301-KIRLRPGGK, A*301-AIFQSSMTK, A*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

Epitope ILKEPVHGV

Immunogen HIV-1 infection
Species (MHC) human (A*0201)
References Spiegel *et al.* 2000

- High levels of CD8+ HIV-1 specific and cytomegalovirus specific CTL were detected by HLA-A*0201-peptide tetramers in 3 infected subjects with very low CD4 counts, but CD8 T cell mediated effector activity was not seen.
- Thus HIV-1 specific CD8+ cells may be present but may lack direct effector activity in late disease, suggesting that overcoming antigen unresponsiveness may be a useful therapeutic strategy.

Epitope `ILKEPVHGV`
Immunogen HIV-1 infection
Species (MHC) human (A*0201)
Keywords epitope processing, immunodominance
References Sewell *et al.* 1999

- Proteasome regulation influences epitope processing and could influence immunodominance.
- The proteasome is inhibited by lactacystin treatment, and gamma IFN induces expression of proteasome subunits, LMP2 and LMP7, which combine with the proteasome to create an immunoproteasome.
- IFN-gamma induction of the immunoproteasome and lactacystin inhibition increases the presentation of the A*0201 VIYQYMDDL epitope, but decreases the presentation of the A*0201 ILKEPVHGV epitope, which is immunodominant within pol proteins, showing the two epitopes are processed by different pathways.
- ILKEPVHGV seems to be processed by the classical proteasome pathway, while VIYQYMDDL appears to be destroyed by this pathway.
- This epitope contains the catalytic site (YMDD) of RT, a conserved sequence in HIV-1 which restricts escape mutants.

References Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFNgamma Elispot assays after vaccination of 5 macaques. The response to the Mamu A*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

Immunogen in vitro stimulation or selection
Species (MHC) human (A*0201)
Keywords epitope processing, dendritic cells
References Andrieu *et al.* 2003

- This study demonstrates that lipopeptides carrying epitopes can be taken up by human dendritic cells, processed using different pathways, and recognized by epitope-specific CD8+ T-cells originally derived from HIV+ individuals. The RT ILKEPVHGV peptide was embedded in a longer peptide fragment in the lipopeptide, and was internalized by endocytosis and processed in the cytosol by proteasomal cleavage by following an endosome-to-cytosol pathway for processing and presentation. Administration of epoxomycin, a proteasome inhibitor, completely abrogated epitope presentation to a CD8+ T-cell line, while monensin, an inhibitor of acid-dependent endosomal enzyme activity did not.
- In contrast to the RT epitope, dendritic cell presentation of the Nef epitope QVPLRPMTYK embedded in a longer peptide in a lipopeptide was not inhibited by epoxomycin, but was inhibited by monensin, indicative of endocytolitic epitope processing.

Species (MHC) human (A*0201)
Assay type Cytokine production, proliferation, Tetramer binding, Intracellular cytokine staining, Chromium-release assay
References Dagarag *et al.* 2003

- Telomer length is short in the CD8+ T-cell compartment of HIV-1 infected people, indicating excessive CTL activation and premature senescense. Here human telomerase RT (hTERT) transduction of HIV-1-specific CTL was used to study the functional impact of telomerase. Telomerase expression enhanced proliferative capacity, as well as cytolytic and antiviral capabilities; cytokine production was unchanged. hTERT transduced CTLs were 10-fold more efficient in controlling HIV-1 replication in culture. Thus telomerase transduction can restore CTL mediated cytolysis, and may have therapeutic potential.
- Three polyclonal CD8+ T-cell lines derived from an HIV-1, HLA A*0201 positive patient were used in this study, including one specific for this epitope. An IV9-specific monoclonal cell line, 68A62 was also generated.

Epitope name IV9
Immunogen HIV-1 infection
Species (MHC) human (A*0201)
Assay type Tetramer binding
Keywords genital and mucosal immunity
References Shacklett *et al.* 2003

- Lymphocytes from rectal biopsies were used to characterize the CD8+ T cell response to HIV in GALT, Gut-associated lymphoid tissues. Patients were selected on the basis of being HLA-A2+ and having detectable SLYNTVATL and ILKEPVHGV tetramer responses in PBMC. SLYNTVATL

CTL CD8+

frequency was increased in GALT relative to PBMC in 6/7 patients studied, while a control response to a CMV-peptide was diminished in GALT. Only two patients had ILKEPVHGV CD8+ T cell responses, and both had slightly higher frequencies in GALT than PBMC.
- HIV may perturb lymphocyte retention in GALT, suggested by an overall reduction of GALT CD8+ cells expressing alphaEbeta7. GALT HIV-specific CD8+ T cells expressed alphaEbeta7, suggesting mucosal priming.

References Singh & Barry 2004
- When A*0201-C3H/J transgenic mice were immunized with plasmids encoding wild-type gag-pol, codon-optimized (CO) gag-pol, and an expression library vaccine expressing 16 fragments of gag-pol fused with ubiquitin for proteosome targeting (ELI), the ELI vaccine produced up to 10-fold higher CD8 T-cell responses than the other two vaccines. In contrast to the wt and CO vaccines, which tended to augment only immunodominant responses, boosting with the ELI vaccine resulted in many CD8 responses against variant epitopes from different HIV-1 clades, and against drug-resistant variants.
- This epitope was recognized in transgenic mice vaccinated with all three vaccine constructs, but the most intense responses were to the ELI vaccine.

References Bennett *et al.* 2007

- Standard assays like ELISpot, ICS and tetramer staining do not measure antiviral activity of HIV-infected CTLs, but use exogenous synthetic peptides on uninfected cells, or HLA tetramers. Similarly, functional avidity assesses CTL activity against uninfected target cells. Here functional avidity is compared to the efficiency of actual infected cells' recognition and killing, revealing a sharp threshold between CTL immune antiviral activity and lack of infected cell recognition.
- As previously shown, epitopes and their variants spanned orders of magnitude of SD50. Likewise, CTL clearance of infected cells varied from 0 to 100% with epitope sequence variation. Moreover, direct suppression of HIV-1 replication by CTLs also varied with epitope variant.
- When killing efficiency (KE) using virus-infected cells was compared to functional avidity using synthetic peptides, there was a narrow threshold separating maximal killing from almost none. Since different SL9-specific clones had similar KEs, which were vastly different from RL10-specific CTL KEs, it was obvious that KEs varied with epitope sequence too. Finally, a strong correlation between KE and inhibition of viral replication was also seen.
- This epitope, ILKEPVHGV, showed marked differences in its functional avidity as well as killing efficiency, when compared to its variants ILKdPVHGV, ILKnPVHGV, ILKdPVHGa, ILKtPVHGV, ILrEPVHGV, ILKEsVHGV, ILKEtVHGV, ILKEPVHGa, ILKEPVHeV, ILKqPVHGV, IiKEPVHGV, ILrtPVHGV, ILKEPVHrV, ILKEPlHGV, kLKEPVHGV and ILKElVHGV.

Keywords dendritic cells
References Zarling *et al.* 1999

- This study compares the ability of macrophages and dendritic cells to stimulate primary responses in CD8+ lymphocytes isolated from HLA-appropriate HIV-uninfected donors using peptide-pulsed APC – the dendritic cells performed better as APC for the stimulation of primary responses.
- Strong CTL responses were elicited by the epitopes DRFYKTLRA and GEIYKRWII when presented by either immature or mature dendritic cells – macrophages were not able to prime a CTL response against DRFYKTLRA.
- A weak response to KLTPLCVSL was stimulated using macrophages as the APC.
- No detectable response was observed for the following previously-defined HIV epitopes: KIRLRPGGK, ILKEPVHGV, IRLRPGGK, GPKVKQWPL.

Epitope ILKEPVHGV
Immunogen computer prediction
Species (MHC) (A2)
Keywords subtype comparisons
References Schafer *et al.* 1998

- This study uses EpiMatrix for T cell epitope prediction to identify possible HLA-B27 and A-2 CTL epitopes in HIV.
- Based on EpiMatrix predictions, 28 peptides were synthesized and tested using T2 binding assays for potential HLA A2 or B27 binding, and 12 of these were shown to bind to the predicted HLA molecule.
- Two of these 12 peptides had been previously identified as CTL epitopes: HLA-B27 KRWILGLNK and HLA-A2 ILKEPVHGV.
- This sequence is not conserved between clades, but is found only in a small number of B clade isolates.

HXB2 Location RT (309–317)

Epitope ILKEPVHGV
Epitope name RT IV9
Immunogen HIV-1 infection
Species (MHC) human (A2)
Keywords binding affinity, subtype comparisons, supertype, computational epitope prediction
References Altfeld *et al.* 2001c

- HIV was scanned for all peptides which carried the A2-supermotif pattern conserved in more than 50% of B clade sequences – 233 peptides met this criteria, and 30 of these bound to HLA-A*0201 – 20/30 bound to at least 3/5 of HLA-A2 supertype alleles tested.
- Three additional previously described HLA-A2 epitopes were added to the set of 20, and 18/22 chronically infected HLA-A2 individuals had CTL that recognized at least one of the 23 peptides (median of 2 and maximum of 6), while 6/12 acute infected individuals recognized at least 1 (median of 1 and maximum of 2)
- This peptide binds to four HLA-A2 supertype alleles: A*0201, A*0202, A*0206 (highest affinity) and A*6802.
- RT IV9 was recognized in 7/22 patients with chronic HIV-1 infection.
- 1/13 patients with acute HIV-1 infection recognized RT IV9.

Species (MHC) human (A2)
Keywords HIV exposed persistently seronegative (HEPS), escape
References Kaul *et al.* 2001c

- This study examines CTL responses in HIV exposed, persistently seronegative individuals, HEPS, who eventually seroconverted – 11/114 HEPS Nairobi sex workers eventually seroconverted, and for six of these HIV CTL reactive epitopes had been defined while seronegative.
- ILKDPVHGV or ILKEPVHGV was recognized in 1 of the 6 women (ML1760), and the response was present in the last available sample prior to seroconversion, 12 months.
- 20/20 sequences of the infecting strain had no substitutions in this epitope, all were ILKDPVHGV, so there was no evidence for escape.
- The epidemiological factor associated with seroconversion was stopping sex work. HIV-specific CTL activity declined when HEPS sex workers stopped working for a period or retired.
- This epitope was recognized by 4/22 HEPS control sex workers: ML887, ML1192, ML1250, and ML1749.

Epitope ILKDPVHGV
Immunogen HIV-1 infection, HIV-1 exposed seronegative
Species (MHC) human (A2)
Keywords subtype comparisons, HIV exposed persistently seronegative (HEPS), immunodominance
References Kaul *et al.* 2001a

- Variants ILK(D/E)PVHGV are A/B clade specific.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.

CTL CD8+

- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-A2 women, 7/10 HEPS and 14/26 HIV-1 infected women recognized this epitope, and ILK(D/E)PVHGV tended to be more reactive in HEPS women, SL(F/Y)NTVATL in infected women.
- The dominant response to this HLA allele was to this epitope in all 7/10 HEPS cases but in only 5 of the 14/26 HIV-1 infected women.
- Four epitopes were considered to be "resistant epitopes", as they were preferentially reactive in HEPS women and so may confer resistance, and these were found in three different proteins: A2 ILK(D/E)PVHGV in RT, A*6802 DTVLEDINL in Protease, B14 DLN(M/T)LN(I/V)V in p24 and B18 FRDYVDRF(Y/F)K also in p24.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.
- Subject ML 1250 had an A2 response to ILK(D/E)PVHGV prior to seroconversion, which switched to SL(F/Y)NTVATL post-seroconversion.
- Subject ML 1760 had an A2 response to ILK(D/E)PVHGV prior to seroconversion, and gained responses to epitopes A2 SL(F/Y)NTVATL and B27 KRWII(L/M)GLNK post-seroconversion.

- Ritonavir (RTV) inhibits chymotryptic activity in the 20S proteasome *in vitro*, as does Saquinavir (SQV) to a lesser extent; Indinavir (IDV) does not. Thus there is concern protease inhibitors may adversely effect CTL epitope processing, but this paper indicates that processing is not inhibited at therapeutically relevant concentrations of RTV when the proteasome is functioning in in an intracellular context.
- RTV did not alter the presentation two RT A2 epitopes processed by distinct pathways: ILKEPVHGV, generated by the constitutive proteasome containing the MB1 beta subunit, and VIYQYMDDL which is dependent on IFNgamma induction of LMP7 which replaces MB1 in the immunoproteasome, and is destroyed by MB1 in the constitutive proteasome.
- RTV did not inhibit the processing and assembly of HLA-B35 or -A2, which are assembled with a rapid and moderate time course, respectively, or of HLA-A3, -B27 and -B39.

Keywords epitope processing
References Cohen *et al.* 2002

- The antigen presentation of two A2-restricted epitopes was compared, SLYNTVATL (p17) and ILKEPVHGV (RT). HIV-1 infected cells were more sensitive to lysis by SLYNTVATL-specific CTL than by ILKEPVHGV-specific CTL, because of a higher density of SLYNTVATL-A2 resulting from differences in processing.
- Incubation with a T1-cell proteolytic extract showed that by four hours, 25% of a p17 peptide had a C-term Leu-85 and were SLYNTVATL-precursors, while ILKEPVHGV-precursors were far less frequent (6.8%) even with four times more proteolytic extract after 30 hours.
- p17 was preferentially cleaved between Leu85 and Tyr86, while appropriate Val484 and Tyr485 cleavage was minor for RT.
- In a competition experiment, RSLYNTVATL bound TAP 3.7-fold more efficiently than RT peptides.
- No difference in CTL avidity was detected in six patients with HLA-A2-restricted responses to these epitopes.
- No significant difference in HLA-A2 binding of to p17 or RT epitopes was observed.

Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Flow cytometric T-cell cytokine assay
Keywords responses in children
References Sandberg *et al.* 2003

- 65 vertically HIV-1 infected children, ages 1-16, the majority undergoing ART, were analyzed in regard to their plasma viremia and CD4+ and CD8+ T cell counts, and CD8+ T cell responses.
- Using vaccina expressed Gag, Pol, Env, Rev, Nef in target cells in an Elispot assay, 85% of the children recognized at least one HIV antigen. The strong CD8+ T cell responses were directed against Pol, followed by Gag and Nef. Children younger than 4 had significantly weaker responses (7/14 had no reponse) than older children (only 1/32 had no response, and responses were greater in magnitude).
- SLYNTVATL and ILKEPVHGV tetramers were used to quantitate specific responses. 49 chlidren in an expanded cohort carried HLA-A2. 1/11 children under 3 years of age had detectable CD8+ T-cell responses to SLYNTVATL, 2/11 to ILKEPVHGV. Among children over 3, 11/38 recognized SLYNTVATL and 9/38 recognized ILKEPVHGV.
- Older children that maintained a CD4 count greater than 400 cells/ul tended to have stronger CTL reponses.

Assay type Cytokine production, CD8 T-cell Elispot - IFNγ, Tetramer binding, Intracellular cytokine staining
Keywords assay standardization/improvement, memory cells
References Sun *et al.* 2003

- This study compares assay methods for testing CTL responses using samples from 20 HIV+ patients. The study compares ELISpot, tetramer-binding, and intracellular IFN-γ. Tetramer-bidning analysis was performed with Gag (SLYNTVATL) or Pol (ILKEPVHGV) tetramers. Antigen presentation using recombinant vaccinia viruses (rVVs) encoding HIV-LAI Gag, Pol, Env, Nef, Tat and Vif proteins was compared to peptide panels. HIV antigen recognition in memory CTLs was measured by chronium release assay and compared to effector/memory CD8+ T cells in an IFN-γ ELISpot assay.

- Results: IFN-γ Elispot and flow cytometry gave similar frequencies of HIV specific CD8+ Tcells. Tetramer-binding analysis was most sensitive. Pools of peptides and the sum of frequencies of individual peptides were comparable. Elispot assays using peptides were more sensitive than assays using vaccinia expressed proteins. Cr release and Elispot against rVVs gave comparable memory cell responses 2/3s of the time.
- 3/7 HLA-A2+ patients recognized this epitope.

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 2/14 CTL T-cell clones tested were specific for RT/IV9. Under conditions of excess peptide (100ug/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 values for the two RT/IV9 clones were very different, 50 and 20,000 pg/ml.

CTL CD8+

References Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

Assay type Tetramer binding, T-cell Elispot
Keywords HIV exposed persistently seronegative (HEPS)
References Missale *et al.* 2004

- HIV-specific T-cell response was tested in patients exposed to blood from a patient with highly replicating HIV; these patients were nosocomially infected with HBV, but uninfected with HIV. HIV-specific T-cell responses were directed to structural and non-structural HIV proteins in 2 patients, suggesting that the virus replicated in these patients sufficiently to prime a cell-mediated immune response that protected them from HIV infection.
- This patient responded to 4/8 HIV epitopes tested in an IFNgamma EliSpot assay or tetramer assay. Responses were detected 8 and 28 weeks after exposure. A response to ILKEPVHGV was detected by both assays.

Assay type CD8 T-cell Elispot - IFNγ
Keywords HIV exposed persistently seronegative (HEPS), immunodominance, genital and mucosal immunity, characterizing CD8+ T cells
References Makedonas *et al.* 2005

- CD8 T-cell responses were studied in individuals who remained seronegative in spite of being mucosally (group 1) or intravenously (group 2) exposed to HIV-1. A similar proportion of subjects from each group recognized at least 1 HIV peptide, and they recognized peptides with similar cumulative intensity. The proportion of responding individuals in both groups was significantly greater than in a low-risk, negative control group. One exposed uninfected subject recognized 7 epitopes.
- HLA-A*0201 epitopes that are immunodominant in chronically infected individuals were rarely stimulatory in exposed uninfected individuals. SLYNTVATL was recognized by one HLA A2+ individual in each group (1/11 vs 1/5), while none of the exposed uninfected individuals tested responded to ILKEPVHGV. In contrast, chronically infected subjects recognized these epitopes at a frequency of 69% and 31%, respectively.

CTL CD8+

References Altfeld *et al.* 2006
- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

References Blondelle *et al.* 2008

- To identify immunogenically optimized peptide epitopes for use in vaccines, two strategies were used. The first studied rare mutant epitopes that were effective in generating a cross-reactive immune response against a range of mutants. The second method was to use a synthetic combinatorial library of peptides and screen for highly effective responses against one epitope (TV9, TLNAWVKVV) and its mutants. Candidate epitopes were tested in HLA-A2 transgenic mice as well as ex vivo human lymphocytes.
- Mutants of epitope IV9 when tested in transgenic mice, showed that the consensus was strongly immunogenic, but the most common mutant, ILKdPVHGV was not especially immunogenic or cross-reactive. Rare mutant, ILKEPVHrV, was highly immunogenic, and cross-reactive to the consensus. Sequences ILrEPiHGV and ILKEPVHGi were also cross-reactive to the consensus. Other mutants were ILKEPVHGa, ILrtPVHGV, IiKEPVHGV, ILrkPVHeV and ILKdPVHkV.

Assay type CD8 T-cell Elispot - IFNγ, Flow cytometric T-cell cytokine assay
Keywords rate of progression, escape
References Geels *et al.* 2003

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occured sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these eptiopes, but this increased over time.

Epitope IKLEPVHGVY
Epitope name B15-IY10(RT)
Immunogen HIV-1 infection
Species (MHC) human (B15)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.

- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Epitope ILKEPVHGVY
Subtype A, B, D
Immunogen HIV-1 infection, vaccine
Vector/Type: DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade *HIV component:* p17 Gag, p24 Gag
Species (MHC) human (B62)
Keywords subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance
References Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFNgamma Elispot assays after vaccination of 5 macaques. The response to the Mamu A*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

Species (MHC) mouse (H-2K^{d})
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining, Other
Keywords subtype comparisons, vaccine-induced epitopes, variant cross-recognition or cross-neutralization, antagonism
References Larke *et al.* 2007

- Cross-clade vaccine recognition was studied using either single-, multi or several anatomically separated single-clade vaccines. Limited cross-clade response was seen with single-clade administrations. Multi-clade vaccines gave immune interference (antagonism and original antigenic sin), reducing CTL response. Simultaneously administered but anatomically separated vaccines from clades A, B, C decreased antagonism and increased immune responses.
- After immunization with any clade vaccine, index epitope RT2, VYYDPSKDLI, was recognized, as well as 2 variants at >70% levels, viz. VYYDPSKDLv and VYYDPtKDLI. Variants VYYDPSKeLI, aYYDPSKeLI, VYYePSKeLI were not recognized.

Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining
Keywords epitope processing, immune evasion, viral fitness and reversion, HLA associated polymorphism
References Honeyborne *et al.* 2007

- To determine whether HLA-B*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.

Immunogen HIV-1 infection
Species (MHC) human (A11)
Keywords subtype comparisons
References Bond *et al.* 2001

- HLA-A11 CRF01 (called subtype E in Bond *et al.*) epitopes were identified that stimulated CTL from HIV+ female sex workers (FSW) from Northern Thailand, of whom more than half were HLA-A11 positive.
- 77 possible HLA-A11 epitopes were first defined using EpiMatrix, these were screened for binding to A11 finding and 26 bound, and 12 of these were epitopes for CTL responses from 8 HLA-A11 positive FSWs, six were novel, six were previously identified.
- This epitope was not predicted by the EpiMatrix method to be likely to bind to A11, though it served as an epitope in the FSWs, and it was one of the six A11 epitopes that had been previously defined.
- 5/8 tested FSWs recognized this epitope.
- This epitope was highly conserved in other subtypes, although exact matches were not very common.

Species (MHC) human (A*2301)
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Species (MHC) human (A*11)
Country Australia, Canada, Germany, United States
Keywords escape, HLA associated polymorphism
References Brumme *et al.* 2008a

- 98 newly infected patients were studied to track early host HLA and Gag/Pol/Nef epitope immune responses' association with viral evolution. Response hierarchies were the same as those for later infection, and 50% of the most rapidly substituting epitopes were restricted by protective HLA, e.g. Gag B*57-associated mutations which were the most rapidly reverting upon transmission to a non-B*57-host. While there are great differences in mutation rates and reversions across the HIV proteome, most early viral change is driven by immune pressure.
- HLA-driven epitope evolution was seen in 80% of published CTL epitopes.
- HLAs-A*11-associated substitution within optimally defined epitope IYQEPFKNLK is at position P5, IYQEpFKNLK. IK10 has a low recognition frequency and escaped once, very early post-infection.

Keywords immunodominance
References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, FKNLKTGKY, is similar to human protein Str Spe Recognition protein, sequence FKNsKTG.

Epitope RMRGAHTNDVK
Epitope name A3-RK11
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A3)

Donor MHC A3, B7, Cw7
Keywords dynamics, supervised treatment interruptions (STI), acute/early infection
References Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 0/14 HLA-A3 positive individuals had detectable A3-restricted responses to this epitope during acute infection, but only 5/15 of HLA-A3 epitopes tested were targeted during acute infection. 5/7 individuals began to have detectable responses to this epitope after STI.

References Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 21% of the study subjects, and it was one of the 25 most frequently recognized peptides.

References Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher interclade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm et al. [J. Virol. 78:2187-2200 (2004)].
- This peptide, QKIAtESIVIWGKTPKFk differs from the consensus C sequence QKIAmESIVIWGKTPKFr at 2 amino acid positions, i.e. by 10.5%.

Keywords binding affinity, immunodominance
References Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, QKIATESIVIWGKTPKFK, had an overall frequency of recognition of 16% - 22% AA, 15.4% C, 9.1% H, 14.3% WI.

References Schellens *et al.* 2008

- Peptide prediction programs based on MHC binding, proteasomal cleavage and TAP transport were applied to select novel epitopes absent from the Los Alamos HIV database. 22 novel epitopes were tested by IFN-gamma ELISpot and 19 (11 HLA-B27 restricted, 8 HLA-B57 restricted) induced strong positive responses.
- Magnitude of response generated was similar to that of previously identified epitopes, but the number of individuals responding was lower. This could be explained by less stringent HLA-typing of subjects and perhaps high sequence variability within these novel epitopes.
- KW9, KLPIWKETW, is a novel HLA-B57-restricted epitope that elicits a CTL IFN-gamma response in the same range as Los Alamos database peptides.

Immunogen HIV-1 infection, vaccine
Vector/Type: DNA *Strain:* B clade *HIV component:* Gag *Adjuvant:* aluminum phosphate

Species (MHC) human
Country United States
Assay type CD8 T-cell Elispot - IFNγ, Other
References Balamurugan *et al.* 2008

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.
- CTL immune response to consensus sequence KLPIQKETWEAWWTE was elicited in subject 00016. Consensus epitope of subjects was rLPIQKETWEAWWmE.

Keywords HAART, ART, supervised treatment interruptions (STI)
References Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (`http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html`) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope

responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient A displayed the greatest response to epitope B14-EL9(gp41), a strong response to B7-TL9(p24), and responses to B7-TM9(Nef) and A32-PW10(RT). Patient B displayed the greatest response to epitope B44-AW11(p24) and also responded to A32-PW10(RT) in both PB and LN samples, while a third response against epitope A32-RW10(gp120) was only detected in the LN sample. Patient D displayed the greatest response to B27-KK10 (p24), and also responded to A30-RY11(p17), A32-PW10(RT), A30-KY11(RT), A32-RW10(gp120), and B18-YY9(Nef).

Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Country South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Other
Keywords supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism
References Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Statistically significant associations between numbers of HLA-8101 expressing subjects and epitope TPPLVKLWYQL were found.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope RT TL11 restriction.

Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining
Keywords binding affinity, immunodominance
References Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV

sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, QLEKEPIVGAETFYVDGA, had an overall frequency of recognition of 15.3% - 22% AA, 11.5% C, 4.5% H, 23.8% WI.

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and there was a close temporal relationship between the number of circulating HIV-specific T cells and viral load was also found.
- All three patients were B*2705, with HLA alleles: A1, A30/31, B*2705, B35; A1, A*0301, B7, B2705; and A*0201, A*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B*2705 epitope KRWIILGGLNK.
- The subject with A*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A*301-RLRPGGKKK, A*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A*0301, B7, B*2705.
- No acute response was detected to the following epitopes: A*201-ILKEPVHGV, A*301-KIRLRPGGK, A*301-AIFQSSMTK, A*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

Epitope `EPIVGAETF`
Immunogen HIV-1 infection
Species (MHC) human (B35)
Country Netherlands
Assay type CD8 T-cell Elispot - IFNγ
Keywords HIV exposed persistently seronegative (HEPS)
References Koning *et al.* 2004
- A high-risk seronegative group of 29 homosexual men showed reduced cellular in vitro susceptibility for HIV infection and enhanced production of RANTES compared to 15 men who went on to seroconvert. Significantly higher frequencies of HLA A*11, A*31 and Cw*15 were also found in the high risk seronegative men. Both groups of men had low frequencies of HIV-1 specific CD8+ T-cells, which may signify exposure more than protection from infection.

CTL CD8+

- No one, 0/3 HLA B35+ infection-resistant men, and 0/5 pre-seroconversion men who went on to become infected, reacted to this epitope.

Country Netherlands
Assay type CD8 T-cell Elispot - IFNγ, Flow cytometric T-cell cytokine assay
Keywords rate of progression, escape
References Geels *et al.* 2003

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occured sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these eptiopes, but this increased over time.

HXB2 Location RT (432–441)
Author Location Pol (587–596)
Epitope EPIVGAETFY
Immunogen HIV-1 infection
Species (MHC) human (B*3501)
References Tomiyama *et al.* 2000a

- CD8+ T-cells that bound one of six HIV-specific B*3501-epitope tetramers did not express CD28 or CD45A.
- A significant increase in CD28-CD45RA- cells and a decrease of CD28+CD45RA+ cells was observed in chronically HIV-1-infected individuals relative to healthy individuals.
- CD28-CD45RA- cells are likely to be effector cells and have high levels of perforin in their cytoplasm.
- The mean percentage of total CD28- CD8+ cells in chronically infected HIV-1-infected patients was 76.6% in comparison to HIV-1-uninfected individuals (40.6%)

Country Barbados, Haiti, United States
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining
Keywords binding affinity, immunodominance
References Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, GAETFYVDGAANRETKL, had an overall frequency of recognition of 18% - 20.3% AA, 11.5% C, 18.2% H, 19% WI.

- An inverse correlation was found between CTL response and viral load.
- Targeted peptides have lower entropy than peptides that are not CTL targeted. This correlation is independent of HLA-restriction.
- Previously described HLA-A26-restricted epitope ETKLGKAGY elicited an immune response in Chinese HIV-1 positive subjects as part of peptides DGAANRETKLGKAGYV and ETKLGKAGYVTNKGRQKV.
- 2 of the 8 HLA-A26 carriers responded to ETKLGKAGY-containing peptide #225 with average magnitude of CTL response of 380 SFC/million PBMC, and to peptide #226 with average magnitude of CTL response of 575 SFC/million PBMC (author communication and Fig.1).

Epitope name Pol606
Immunogen HIV-1 infection, vaccine
Vector/Type: peptide *HIV component:* RT
Adjuvant: Incomplete Freund's Adjuvant (IFA)
Species (MHC) human (A2)
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords binding affinity, subtype comparisons, computational epitope prediction
References Corbet *et al.* 2003

- HLA-A2-restricted HIV-1 CTL epitopes were computationally predicted. Binding affinities for HLA-A*0204, immunogenicity in HLA-A*0201 transgenic mice, and responses to the peptides in 17 HIV-1 infected patients were tested. 31 novel conserved A2 epitopes were detected. An average of 4 epitopes were recognized per patient.
- This peptide was an intermediate A2 binder that did not induce CTL or CD8+ T-cell IFN gamma responses in transgenic mice. Responses were detected in 2/17 HIV+ HLA-A2 subjects.

- 11 HLA-A2+ (A*0201, A*0220, A*0234 or A*0236), patients' HIV were sequenced. Of 28 epitopes studied, most were conserved and elicited a subdominant CTL response. 9 epitopes in 7 proteins showed T-cell cross reaction. These epitopes were optimized to induce more immunogenic but cross-reacting responses.
- Epitopes in Gag, Pol, Env, Nef were more conserved than epitopes in shorter proteins Vpu, Vif, Vpr and Rev. Most natural epitopes were untargeted or targeted by 1 or 2 patients.
- Pol 606 KLGKAGYVT epitope was found in 7 patients but only 2 had CTL immune responses to it. Lack of recall response in 5 patients could be due to lack of processing or immune subdominance.
- Though poorly immunogenic in A2 tg mice, was anchor-optimization of natural Pol 606(9T) to Pol606(9V), KLGKAGYVv, induced cross-reaction and higher immunogenicity.

CTL CD8+

Keywords rate of progression, escape, acute/early infection
References Fomsgaard *et al.* 2008

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.
- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Pol epitope KLGKAGYVT, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients. DK1 had sequence variant rLGKAGYVT.

References Pérez *et al.* 2008

- Bioinformatic prediction using NetCTL 1.0, Episelect and NetMHCpan generated 184 CTL epitopes from Gag, Pol, Nef, Env and Tat in HIV subtypes A, B, C, D and CRF01_AE, restricted by MHC A1, A2, A3, A24, B7, B44 and B58. 45 of the 114 epitopes recognized experimentally in subjects were novel, and an elite subgroup comprising 21 epitopes were recognized by at least 13% of patients tested.
- Response magnitude was high—Gag and Nef, Env, Tat in descending order). While Gag, Pol, Env and Nef were highly immunocgenic, only 38% Tat epitopes elicited a response.
- 4 patterns of cross-subtype recognition found were (a) conserved epitopes recognized by patients infected with several HIV subtypes (b) infrequently found reference epitopes recognized by patients infected with several HIV subtypes (c) epitopes more prevalent in certain subtypes recognized by patients infected with several subtypes (d) rarely, subtype-specific epitopes unable to elicit cross-clade recognition
- Epitope LTDTTNQKT was recognized by at least 4 patients with restricting HLA supertype and infected with several HIV subtypes. Predicted HLA restriction for this epitope was to suptertype A1.

References Balamurugan *et al.* 2008

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.

- CTL immune response to consensus sequence TDTTNQKTELQAIHL was elicited in subject 00016. Consensus epitope of subjects was the same as Clade B consensus.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A*11-restricted epitopes were recognized less frequently than other epitopes, and A*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, ALQDSGLEV, was detected within overlapping peptides QKTELQAIHLALQDSGL and IHLALQDSGLEVNIV.

CTL CD8+

Subtype B
Immunogen vaccine
Vector/Type: DNA *Strain:* multiple epitope immunogen *HIV component:* p17/p24 Gag, Pol *Adjuvant:* IL-12
Species (MHC) transgenic mouse (A2)
Assay type Cytokine production, CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords vaccine-specific epitope characteristics, vaccine antigen design
References Bolesta *et al.* 2005

- Immunization of transgenic mice with a codon-optimized hGagp17p24-Polp51 DNA plasmid, consisting of clusters of highly conserved CTL epitopes presented by multiple MHC class I alleles, induced 2- to 5-fold higher CD8+ T-cell responses than the corresponding full-length proteins. The modified proteins had the ribosomal frameshift deleted, as well as the potentially immunosuppressive p15, and protease and integrase. This correlated with higher protection against challenge with Gag and Pol expressing recombinant vaccinia virus. Mice immunized with the hGagp17p24-Polp51 also showed an elevated level of type 1 cytokine production as well as an increased titer of p24- and RT-specific IgG2 antibody responses.
- This was 1 of 4 A2 gag/pol epitopes tested. Transgenic mice immunized with the deleted construct induced more potent EliSpot reactions to this epitope than those immunized with full length Gag/Pol.

Species (MHC) human
Assay type CD8 T-cell Elispot - IFNγ
Keywords immunodominance
References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, VNIVTDSQYA, is similar to human protein HERV, sequence VNIyTDSQYA and human protein Thrombospondin 3 precursor, sequence VNtVTDddYA.

Epitope QIIEQLIKK
Subtype B, CRF01_AE
Immunogen HIV-1 infection
Species (MHC) human (A*1101)
Keywords subtype comparisons, TCR usage
References Fukada *et al.* 2002

- Counterparts for eight known clade B HLA A*1101 epitopes were generated for clade E (CRF01). Three epitopes, identical among clade A-E, were cross-reactive and recognized by clade E infected individuals. The clade E and B analogs to three more HLA A*1101 epitopes was recognized in a clade specific manner. Two other HLA A*1101 clade B defined epitopes were found not to have stimulated a response in clade E infected individuals.
- QIIEQLIKK was found to elicit clade-specific responses in clade B (QIIEQLIKK is most common) and clade E (qiieElikk is most common). QIIEQLIKK was strongly recognized by CTL from 1/5 B clade infected Japanese subjects, and qiieElikk from 3/7 E clade infected Thai subjects. The variant qiieKliEk, common in the A subtype, was also recognized in 2/7 E clade infected Thai subjects.
- The binding of QIIEQLIKK, qiieElikk and qiieKliEk to HLA A*1101 was similar, but CTL clones from individuals did not cross-react with the cross-clade peptides indicating that the substitutions inhibited TCR interaction.

Donor MHC A11, A2, B18, B44, Cw12, Cw5
Country United States
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining, Flow cytometric T-cell cytokine assay
Keywords optimal epitope
References Allen *et al.* 2005b

- 4/14 optimal HIV-1 T-cell epitopes in a subject underwent mutation associated with dramatic loss of the original CD8 response. For 1 of the escape variants, a novel CD8 T-cell response equal in magnitude to the wildtype, was generated. CD8 T-cell recognizing the variant epitope utilized a distinct T-cell receptor and did not exhibit any cross-reactivity against the wildtype.
- This epitope did not vary.

Immunogen HIV-1 infection
Species (MHC) human (A2)
Country Denmark
Assay type Flow cytometric T-cell cytokine assay
Keywords rate of progression, escape, acute/early infection
References Fomsgaard *et al.* 2008

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.
- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Pol epitope YLAWVPAHK, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients. DK1 had sequence variant YLsWVPAHK.

HXB2 Location RT (532–540)
Author Location Pol (714–722)
Epitope YLAWVPAHK
Immunogen HIV-1 infection
Species (MHC) human (A3 supertype)
Keywords supertype, rate of progression
References Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind 5/5 HLA-A3 supertype alleles (A*0301, A*1101, A*3101, A*3301 and A*6801).

Keywords HLA associated polymorphism
References Rousseau *et al.* 2008

- 3 phylogenetic correction methods—MLL (maximum likelihood character state analysis followed by likelihood ratio test), MLF (maximum likelihood character state analysis followed by Fisher test), and parsimony character state analysis were used to identify points in the HIV-1 subtype C proteome that conferred susceptibility or resistance to CTLs. Associations of HLA-epitope combinations that were inferred to be susceptible or resistant were organized into immunological sets that would help identify the best residues and genes as candidates for vaccines. While all proteins were interrogated, Gag, Pol, Env and Nef were focused upon. Amino acid changes were evaluated for association with plasma viral load.
- Proteome maps may be seen at `http://www.hiv.lanl.gov/content/immunology/hlatem/study5/index.html` with information showing single or multiple sites involving escape and reversion.
- HLA- B and -C alleles associated more with aa changes than HLA-A, suggesting that the former two are more important in driving viral evolution.
- The ratio of susceptible to resistant residues in HIV proteins was in descending order, Vpr>Gag>Rev>Pol>Nef>Vif>Tat>Env>Vpu, showing that epitopes from the earlier proteins are more conserved owing to viral fitness cost upon mutation.
- This previously described Pol HLA B*4403-restricted epitope, QEEHEKYHSNW was susceptible at E2. Variants QaEHEKYHSNW, QdEHEKYHSNW, QgEHEKYHSNW, and QvEHEKYHSNW were resistant to CTL response, but associated with lower viral loads. This epitope is 1 of 7 that suggest a fitness cost to immune escape.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope RAMASDFNL was predicted to be restricted by HLA A*0201, B*2709 and C*0304

Epitope LPPIVAKEI
Epitope name LI9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B*51)
Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, HLA associated polymorphism
References Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore et al., Science 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- There are two variant forms of this B57/B5801 epitope at the second position, LPPiVAKEI and LPPvVAKEI. Leslie et al., J Exp Med. 201:891 (2005) suggest that the escape form LPPvVAKEI may have come to dominate the B clade lineage over time due to higher HLA B51 frequencies in B clade epidemic regions. Bhattacharya suggests lineage effects are also playing an important role in the observed amino acid frequencies, and note that the ratio of I/V has not change over time, and that the frequency of I/V in different epidemic populations does not correlate with HLA B51 allele frequency.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

Epitope LPPVVAKEI
Immunogen HIV-1 infection
Species (MHC) (B*5101)
Assay type Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay, CTL suppression of replication
Keywords binding affinity, class I down-regulation by Nef, rate of progression
References Tomiyama *et al.* 2005

- HLA-B*5101 associated with slow progression to the disease state was studied as related to Nef-mediated HLA class I downregulation. It was shown that different CTLs have different ranges of ability to kill HIV-1 infected CD4+ T cells and suppress HIV-1 replication. This was found to be a function of the specific HIV-1 epitope presented by the corresponding HLA allele to the CTL.
- Certain epitope-recognising CTL clones or lines were therefore capable of killing HIV-1 infected cells even in the presence of Nef-mediated MHC 1 downregulation, while other CTL clones recognising different epitopes were not so capable.
- There was no significant difference in cytokine production or cytokine producing cells between CTLs that were capable of killing CD4+ T-cells infected with HIV-1 and those CTLs that could not kill such HIV-1 infected cells.
- On the basis of studies involving binding abilities and cytolytic activities for four different epitopes that correlate with HLA-B*5101-restricted CTLs, it is suggested that the ability of CTLs to kill infected CD4+ T cells is due to the number of epitopes presented by the HLA on the surface of the CD4+ T cells rather than the ability of TCR to recognise the epitope.

References Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.

CTL CD8+

- Statistically significant associations between numbers of HLA-4201 expressing subjects and epitope LPPIVAKEI were found.
- A strong association between B*4201 and variation in this epitope, LI9, was found.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A*11-restricted epitopes were recognized less frequently than other epitopes, and A*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, QVDCSPGI, of unknown HLA restriction, was detected within overlapping peptides LKGEAMHGQVDCSPGIW and GQVDCSPGIWQLDCTHL.

References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, YIEAEVIPA, is similar to an unnamed human protein, sequence gYIEAaVIPAG and human protein p53 inducible protein, sequence EIEAEV.

Epitope ETAYFILKL
Subtype A
Immunogen HIV-1 exposed seronegative
Species (MHC) human (A*6802)
References Kaul *et al.* 2000
- 11/16 heavily HIV exposed but persistently seronegative sex-workers in Nairobi had HIV-specific CD8 gamma-IFN responses in the cervix – systemic CD8+ T cell responses tended to be to the same epitopes but at generally lower levels than cervical CD8+ T cell responses.
- Low risk individuals did not have such CD8+ cells.
- CD8+ T cell epitopes: DTVLEDINL (3 individuals), SLYNTVATL (4 individuals), LSPRTLNAW (3 individuals) and YPLTFGWCF (4 individuals) were most commonly recognized by the HIV-resistant women.

Epitope ETAYFILKL
Immunogen HIV-1 infection, HIV-1 exposed seronegative
Species (MHC) human (A*6802)
Keywords HIV exposed persistently seronegative (HEPS), immunodominance
References Kaul *et al.* 2001a
- ETAYFILKL cross-reacts with clades A, B and D.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-A*6802 women, 3/12 HEPS and 9/11 HIV-1 infected women recognized this epitope likelihood ratio 7.9, p value 0.01, and HEPS women tended to respond to DTVLEDINL, while infected women to ETAYFILKL.

CTL CD8+

- The dominant response to this HLA allele was to this epitope in 2 of the 3/12 HEPS cases and in all 9/11 HIV-1 infected women that responded to the epitope.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.
- Subject ML 1203 started with CTL responses to A*6802 DTVLEDINL and to B7 FPVTPQVPLR prior to seroconversion, and upon seroconversion acquired additional responses to A*6802 ETAYFILKL which became dominant, B7 TPGPG(V/I)RYPL, B7 IPRRIRQGL, and B7 SPRTLNAWV.
- Subject ML 1707 started with a CTL response to A*6802 DTVLEDINL prior to seroconversion, and switched to A*6802 ETAYFILKL and A24 RDYVDRFFKTL post-seroconversion.
- Subject ML 1830 made no detectable response prior to seroconversion, but responded to A*6802 DTVLEDINL and A*6802 ETAYFILKL post-seroconversion.

Epitope STTVKAACWW
Epitope name B57-SW10(Int)
Immunogen HIV-1 infection
Species (MHC) human (B57)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Immunogen HIV-1 infection
Species (MHC) human (B*5801, B57)
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords responses in children, mother-to-infant transmission, characterizing CD8+ T cells
References Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

HXB2 Location Integrase (127–135)
Author Location Pol (869–877)
Epitope KAACWWAGI
Immunogen HIV-1 infection
Species (MHC) human (A2 supertype)
Keywords supertype, rate of progression
References Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.

CTL CD8+

- This epitope can bind three of the five HLA-A2 supertypes alleles (A*0201, A*0202, A*0203, A*0206 and A*6802).

Keywords TCR usage, structure, characterizing CD8+ T cells
References Gillespie *et al.* 2006

- CD8+ T cell repertoire recognizing KAFSPEVIPMF [KF11] and variants and the structure of individual B*57-peptide complexes were studied.
- In addition, immunodominancy of the previously mapped B*57 epitopes during chronic infection was assessed. KGFNPEVIPMF and ISPRTLNAW were immunodominant both in frequency and magnitude of recognition.

Epitope KTAVQMAVF
Immunogen HIV-1 infection
Species (MHC) human (B*5801, B57)
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords responses in children, mother-to-infant transmission, escape
References Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

Country United States
Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords binding affinity, supertype, vaccine-specific epitope characteristics, cross-presentation by different HLA

References Wilson *et al.* 2003

- 21 supertype-A2, -A3 and -B7-restricted epitopes predicted to be immunogenic by HLA-peptide binding motifs and phenotypic frequency in individuals were recognized by HIV-1 + subjects in ELISpot assays and shown to bind with high affinity to minimum 3 HLA-alleles of the restricting supertype. These epitopes were included in DNA vaccine EP HIV-1090 that avoided immunodominant responses and did not restrict subject immunity to predicted HLA-type when tested in mice. Transgenic mice mounted a vaccine-response similar to that induced by ELISpot assay in humans.
- Epitope QMAVFIHNFK of the HLA-A3 supertype bound most strongly to HLA-A*1101, -A*0301 and -A*3101 and also to -A*6801 and -A*3301. It was conserved 100% in subtype A, 100% in B, 88% in C and 100% in subtype D. 4/23 HLA-A3 supertype expressing HIV-1 + subjects mounted a positive ELISpot response to Pol929.

Species (MHC) human (A*0301)
Assay type Cytokine production, CD8 T-cell Elispot - IFNγ, Chromium-release assay, Other, HLA binding
Keywords vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism
References Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to published restriction above, epitope AVFIHNFKR was predicted to be restricted by HLA A*0301, A*1101, A*3101, A*3301, A*6601 and A*6801.

References Wang *et al.* 2007c

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA

CTL CD8+

type in China, A*11-restricted epitopes were recognized less frequently than other epitopes, and A*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This putative epitope, AVFIHNFKRK, was detected and confirmed within overlapping peptides AVFIHNFKRKGGIGGYSA and RKGGIGGYSAGERIVDII.

CTL CD8+

Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Assay type CD8 T-cell Elispot - IFNγ
Keywords computational epitope prediction
References Schellens *et al.* 2008
- Peptide prediction programs based on MHC binding, proteasomal cleavage and TAP transport were applied to select novel epitopes absent from the Los Alamos HIV database. 22 novel epitopes were tested by IFN-gamma ELISpot and 19 (11 HLA-B27 restricted, 8 HLA-B57 restricted) induced strong positive responses.
- Magnitude of response generated was similar to that of previously identified epitopes, but the number of individuals responding was lower. This could be explained by less stringent HLA-typing of subjects and perhaps high sequence variability within these novel epitopes.
- KY9, KRKGGIGGY, is a novel HLA-B27-restricted epitope that elicits a CTL IFN-gamma response significantly higher than that of Los Alamos database peptides.

Epitope GERIVDII
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Country China
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining, Other
Keywords assay standardization/improvement, optimal epitope
References Wang *et al.* 2007c
- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A*11-restricted epitopes were recognized less frequently than other epitopes, and A*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, GERIVDII, of unknown HLA restriction, was detected within overlapping peptides RKGGIGGYSAGERIVDII, SAGERIVDIIATDIQTK and DIIATDIQTKELQKQITK.

Epitope QKQITKIQNFRVYYR
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression
References Bailey *et al.* 2008

- This is the first documentation of transmission of HIV-1 from a patient who developed AIDS (Progressor) to an Elite Suppresssor (ES).
- Both patients are HLA-B*5703-positive. The ES also has B*27 allele. Escape mutations in HLA-B*57-restricted epitopes were present in both patients, suggesting that they by themselves cannot explain the difference in the outcomes.
- The study concluded that viral replication is controlled in ES by at least two mechanisms: (i) direct inhibition of viral replication by polyfunctional HIV-1 specific CD8+ T cells that proliferate in response to autologous viral peptides; (ii) selection for and maintenance of escape mutations that have a negative impact on viral fitness.
- This epitope elicited IFN-γ response in the Progressor.

Epitope TKIQNFRVYY
Subtype B, C
Immunogen HIV-1 infection
Species (MHC) human (B*1503)
Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, rate of progression, immunodominance
References Frahm *et al.* 2006

- CTL responses restricted by HLA-B*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects inspite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominanat CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.
- TKIQNFRVYY of clade B is a potential HLA-B*1503-restricted epitope, with epitope iKIQNFRVYY found in clade C.

Species (MHC) human
Country United States
Assay type CD8 T-cell Elispot - IFNγ, Other
References Balamurugan *et al.* 2008

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.
- CTL immune response to consensus sequence TKIQNFRVYYRDSRD was elicited in subject 00016. Consensus epitope of subject 00015 was the same as Clade B consensus and of subject 00016 was TKIQNFRVYYRDhRD.

Epitope TKIQNFRVYYRDSRDPLW
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Assay type T-cell Elispot
Keywords supervised treatment interruptions (STI), immunodominance, early treatment
References Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.

- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 21% of the study subjects, and it was one of the 25 most frequently recognized peptides.

Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Keywords vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism
References Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.

CTL CD8+

- In addition to the published restriction above, epitope KIQNFRVYY was predicted to be restricted by HLA A1 and A*3002.

Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope LLWKGEGAV was predicted to be restricted by HLA A*0201, A*0204, A*0205 and A*0209.

CTL CD8+

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, KVVPRRKAKIIRDYGKQM, had an overall frequency of recognition of 15.3% - 20.3% AA, 7.7% C, 9.1% H, 19% WI.

References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.

- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

References Frahm *et al.* 2006

- CTL responses restricted by HLA-B*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects inspite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominanat CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.
- RKAKIIRDY of clade B is a potential HLA-B*1503-restricted epitope, with epitope RKAKIIkDY found in clade C.

Keywords supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism
References Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Statistically significant associations between numbers of HLA-4201 expressing subjects and epitope KIIKDYGKQM were found.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope KM10 restriction.

Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A2)
Keywords epitope processing, escape
References Moore *et al.* 2002b

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- 25 negative associations were also found between polymorphism and HLA alleles. The authors propose this is due to escape mutations in epitopes presented by common HLA types dominating in the population, and give examples of five amino acids which are in the consensus and tend to be stable in those with the most common HLA allele, HLA-A2.

Epitope
Immunogen HIV-1 exposed seronegative
Species (MHC) human
Keywords review, HIV exposed persistently seronegative (HEPS)
References Rowland-Jones *et al.* 2001

- This is a review that summarizes observations about HIV-specific CTL found in the HIV-1 exposed persistently seronegative (HEPS) population.
- The CTL responses assayed by ELISPOT and by CTL precursor frequencies by limiting dilution analysis indicate that CTL in HEPS individuals tend to be of a lower magnitude than in chronic HIV-1 infections – the responses in HEPS cases are below the level of detection by tetramer assays.
- CD8+ CTL responses tend to be detectable in HEPS subjects only if they are recently exposed, and the response diminishes if exposure is reduced – it is not clear if there is a stable memory population in HEPS cases.
- CD8+ CTL responses in the HEPS population are associated with HIV-1 specific CD4+ T cell responses, assayed by proliferation assays, IL-2 secretion, and ELISPOT, and the authors consider the possibility that HIV-1-specific T-help responses improve the "quality" of the CD8+ response in HEPS individuals relative to HIV-1 infected individuals, who tend to have a poor HIV-1-specific T-help response.
- HIV-1 specific CD8+ CTL responses in HIV-1 infected individuals show reduced levels of perforin, and the T cells may not mature properly, and although similar studies have not been conducted in HEPS individuals this is considered as a possible difference in the CTL immune response in HEPS and HIV-1 infected people.

Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed; however, epitopes were not found that span the invariant, most highly conserved regions of RT and Protease. This might be due to the virus evolving conserved features that disallow the CTL responses in these most conserved regions, as functional constraints for enzyme function would not tolerate change, and normal capacity for immune escape by rapid evolution is lost in these domains.

Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Keywords rate of progression, acute/early infection
References Fomsgaard *et al.* 2008

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.
- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Vif epitope SLVKHHMYV, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients.

Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Epitope SQ/KRASGQFY/F
Subtype C
Immunogen HIV-1 infection
Species (MHC) human (B*1503)
Keywords HLA associated polymorphism
References Rousseau *et al.* 2008

- 3 phylogenetic correction methods—MLL (maximum likelihood character state analysis followed by likelihood ratio test), MLF (maximum likelihood character state analysis followed by Fisher test), and parsimony character state analysis were used to identify points in the HIV-1 subtype C proteome that conferred susceptibility or resistance to CTLs. Associations of HLA-epitope combinations that were inferred to be susceptible or resistant were organized into immunological sets that would help identify the best residues and genes as candidates for vaccines. While all proteins were interrogated, Gag, Pol, Env and Nef were focused upon. Amino acid changes were evaluated for association with plasma viral load.
- Proteome maps may be seen at `http://www.hiv.lanl.gov/content/immunology/hlatem/study5/index.html` with information showing single or multiple sites involving escape and reversion.
- HLA- B and -C alleles associated more with aa changes than HLA-A, suggesting that the former two are more important in driving viral evolution.
- The ratio of susceptible to resistant residues in HIV proteins was in descending order, Vpr>Gag>Rev>Pol>Nef>Vif>Tat>Env>Vpu, showing that epitopes from the earlier proteins are more conserved owing to viral fitness cost upon mutation.
- This previously described Vif HLA B*1503-restricted epitope, SQ/KRASGQFY/F was susceptible at K2. Variants SgRASGQFY/F, SqRASGQFY/F and SrRASGQFY/F were resistant to CTL response, but associated with lower viral loads. This epitope is 1 of 7 that suggest a fitness cost to immune escape.

Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Epitope HPKVSSEVHI
Epitope name HI10
Subtype C
Immunogen HIV-1 infection
Species (MHC) human
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Other
Keywords supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism
References Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Statistically significant associations between numbers of HLA-4201 expressing subjects and epitope HPKVSSEVHI were found.

- Functional avidity is correlated with selection pressure observed in HLA allele-epitope HI10 restriction

Immunogen HIV-1 infection
Species (MHC) human
Country China
Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, immunodominance
References Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher interclade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm et al. [J. Virol. 78:2187-2200 (2004)].
- This peptide, LVItTYWGLhtGERDWHL differs from the consensus C sequence LVIkTYWGLqtGERDWHL at 3 amino acid positions, i.e. by 16.7%.

Keywords acute/early infection, variant cross-recognition or cross-neutralization, superinfection
References Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- The response to this epitope, HTGERDWHL, was present before superinfection but waned afterward. The epitope from the first strain had the substitution hPgerdwhl, while the second strain matched the test peptide.

- 11 HLA-A2+ (A*0201, A*0220, A*0234 or A*0236), patients' HIV were sequenced. Of 28 epitopes studied, most were conserved and elicited a subdominant CTL response. 9 epitopes in 7 proteins showed T-cell cross reaction. These epitopes were optimized to induce more immunogenic but cross-reacting responses.
- Epitopes in Gag, Pol, Env, Nef were more conserved than epitopes in shorter proteins Vpu, Vif, Vpr and Rev. Most natural epitopes were untargeted or targeted by 1 or 2 patients.
- Vif 101 (9L) GLADQLIHL epitope was not found in any patients but 2 patients had immune responses to it.
- 7 CTL cross-reacting variants were tested: they were L9I (GLADQLIHi), L9M (GLADQLIHm), G1S (sLADQLIHL), G1N (nLADQLIHL), G1D (dLADQLIHL), G1E (eLADQLIHL) and G1H.L9Q (hLADQLIHq). 8 of 11 patients cross-reacted with G1N and G1D. A2tg mice immunized with Vif101 also induced cross-reacting CTL to L9I, G1S, L9M and to a lesser extent to G1E, G1H.L9Q.
- Vif101 (9L)-induced CTLs cross-reacted to Vif101 (9M) which though not found in any of the Danish isolates studied, is common worldwide among clade C (70%), clade D (35%) and clade H (33%) HIV-1-isolates.

Epitope GLADQLIHL
Epitope name Vif 101 (9L)
Immunogen HIV-1 infection
Species (MHC) human (A2)
Country Denmark
Assay type Flow cytometric T-cell cytokine assay
Keywords rate of progression, escape, acute/early infection
References Fomsgaard *et al.* 2008

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.

- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Vif epitope GLADQLIHL, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients. DK1 had variant sequence dLADQLIHL.

Immunogen HIV-1 infection
Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.
- CTL immune response to consensus sequence RNAILGHIVSPRCEY was elicited in subject 00015. Consensus epitope of subject 00015 was RNAILGHvVSPiCdY and of subject 00016 was RNAILGrIVSPRCEY.

References Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance

of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

References Zhai *et al.* 2008

- 49 ART-naive chronically HIV-1 infected Chinese subjects' CTLs were tested with 413 OLPs in IFN-gamma assays, determining optimal epitopes specific for Chinese Clade B HIV-1 sequences.
- An inverse correlation was found between CTL response and viral load.
- Targeted peptides have lower entropy than peptides that are not CTL targeted. This correlation is independent of HLA-restriction.
- The tested peptide sequence, TALTTPKkIKPPLPSVrK, contains a variant, KiKPPLPSVrK that differs by 2 substitutions from the previously described HLA-A3 epitope KTKPPLPSVKK. None of the 3 HLA-A3 carriers responded to the variant KiKPPLPSVrK.

HXB2 Location Vif (160–169)

Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B57)
Country Netherlands
Assay type CD8 T-cell Elispot - IFNγ
Keywords computational epitope prediction
References Schellens *et al.* 2008

- Peptide prediction programs based on MHC binding, proteasomal cleavage and TAP transport were applied to select novel epitopes absent from the Los Alamos HIV database. 22 novel epitopes were tested by IFN-gamma ELISpot and 19 (11 HLA-B27 restricted, 8 HLA-B57 restricted) induced strong positive responses.
- Magnitude of response generated was similar to that of previously identified epitopes, but the number of individuals responding was lower. This could be explained by less stringent HLA-typing of subjects and perhaps high sequence variability within these novel epitopes.
- VW9, VTKLTEDRW, is a novel HLA-B57-restricted epitope that elicits a CTL IFN-gamma response in the same range as Los Alamos database peptides.

HXB2 Location Vif (168–176)

Epitope DQGPQREPY
Subtype B
Immunogen HIV-1 infection, peptide-HLA interaction
Species (MHC) human
Assay type CD8 T-cell Elispot - IFNγ
Keywords immunodominance
References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, DQGPQREPY, is similar to human protein Carcinoma associated protein, sequence qRPDQGPQRPP, and human proline-rich protein, sequence DQGPQRpP.

References Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher interclade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.

- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm et al. [J. Virol. 78:2187-2200 (2004)].
- This peptide, GPQREPYNEWTLELLEEL differs from the consensus C sequence GPQREPYNEWTLELLEEL at 0 amino acid positions, i.e. the two clades' peptides are identical.

Epitope REPHNEWTL
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.

- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

References Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, ELKNEAVRHFPRIWLHSL, had an overall frequency of recognition of 25.3% - 32.2% AA, 19.2% C, 20.5% H, 23.8% WI. This peptide is included in a 27 aa Vpr highly reactive region to be used for vaccine design.

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- Last position (9)in the epitope had potentially experienced positive selection. EAVRHFPRt and EAVRHFPRl escape variants were found.

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

Epitope EAVRHFPRI
Epitope name EI9(Vpr)
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Country China
Assay type CD8 T-cell Elispot - IFNγ
Keywords non-susceptible form
References Zhai *et al.* 2008

- 49 ART-naive chronically HIV-1 infected Chinese subjects' CTLs were tested with 413 OLPs in IFN-gamma assays, determining optimal epitopes specific for Chinese Clade B HIV-1 sequences.
- An inverse correlation was found between CTL response and viral load.
- Targeted peptides have lower entropy than peptides that are not CTL targeted. This correlation is independent of HLA-restriction.

- The tested peptide sequence, ELKREAVRHFPRpWLHGL, contains a variant, EAVRHFPRp that differs by 2 substitutions from the previously described HLA-B51 epitope EAVRHFPRI. None of the 15 HLA-B51 carriers responded to the variant EAVRHFPRp.

Epitope EAVRHFPRIWLHGLG
Immunogen HIV-1 infection, vaccine
Vector/Type: canarypox prime with gp120 boost *Strain:* B clade LAI, B clade MN *HIV component:* Gag-Pol, gp120, gp41
Species (MHC) human
Donor MHC A*2501, A*3002; B*0702, B*1801
Assay type CD8 T-cell Elispot - IFNγ, Flow cytometric T-cell cytokine assay
Keywords vaccine-induced epitopes
References Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromized by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

Epitope AVRHFPRIW
Epitope name AW9
Immunogen HIV-1 infection
Species (MHC) human (B*57)
Assay type CD8 T-cell Elispot - IFNγ
Keywords escape
References Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite supressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- HLA-B*57-restricted optimal epitope AVRHFPRIW was tested for immune response.

HXB2 Location Vpr (30–38)
Author Location Vpr (30–38)
Epitope AVRHFPRIW
Epitope name vprAV9
Immunogen HIV-1 infection
Species (MHC) human (B*57)
Country United Kingdom, Kenya
Assay type CD8 T-cell Elispot - IFNγ
Keywords TCR usage, structure, characterizing CD8+ T cells
References Gillespie *et al.* 2006

- CD8+ T cell repertoire recognizing KAFSPEVIPMF [KF11] and variants and the structure of individual B*57-peptide complexes were studied.
- In addition, immunodominance of the previously mapped B*57 epitopes during chronic infection was assessed. KGFNPEVIPMF and ISPRTLNAW were immunodominant both in frequency and magnitude of recognition.

HXB2 Location Vpr (30–38)
Author Location Vpr (29–38 SF2)
Epitope AVRHFPRIW
Immunogen HIV-1 infection
Species (MHC) human (B*5701)
Keywords acute/early infection
References Altfeld *et al.* 2001a

- CTL responses against HIV-1 Vpr, Vpu, and Vif were analyzed in multiple HIV-1-infected individuals.
- This epitope was recognized by 4/6 individuals expressing B*5701 allele.
- Individuals with long-term nonprogressive and treated chronic HIV-1 infection targeted Vpr more frequently than individuals with treated acute infection.
- Vpr is a frequent target of HIV-1 specific CD8+ T-cells – a response was detected in 45% of individuals tested and Vpr and p17 were the most preferentially targeted proteins per unit length by CD8+ T-cells.

HXB2 Location Vpr (30–38)

CTL CD8+

Author Location Vpr (29–38)
Epitope AVRHFPRIW
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B*5701)
Keywords early-expressed proteins
References Addo *et al.* 2002b

- CTL responses against regulatory and accessory proteins in 70 HIV-1 infected patients were studied using overlapping peptides and Elispot.
- 28% targeted one or more overlapping Tat peptides; 36%, Rev peptides; 33%, Vif peptides; 40%, Vpr peptides; and 2%, Vpu peptides.
- All known optimally defined epitopes were summarized for the five proteins.

Immunogen HIV-1 infection
Species (MHC) human (B*5801, B57)
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords responses in children, mother-to-infant transmission, escape
References Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

HXB2 Location Vpr (30–38)
Author Location Vpr
Epitope AVRHFPRIW
Subtype B, C
Immunogen HIV-1 infection
Species (MHC) human (B57, B63)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, cross-presentation by different HLA, optimal epitope
References Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- This epitope was recognized by 30% of B63-positive subjects and 14% of B57/58-positive subjects.

Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Keywords rate of progression, escape, acute/early infection
References Fomsgaard *et al.* 2008

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.

- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Vpr epitope FPRPWLHGL, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients. DK1 had variant sequence FPRPWLHsL.

References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

References Frahm *et al.* 2007b

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- In addition to its known HLA associations (B07, B81), an additional HLA (B42) was statistically predicted to be associated with this epitope.

HXB2 Location Vpr (34–42)
Author Location Vpr (34–42)
Epitope FPRIWLHGL
Epitope name B7-FL9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B7)
Donor MHC A3, B7, Cw7
Keywords dynamics, supervised treatment interruptions (STI), acute/early infection
References Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 1/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 2/4 individuals had detectable responses to this epitope after STI.

HXB2 Location Vpr (34–42)
Author Location Vpr (34–42)
Epitope FPRTWLHGL
Epitope name B7-FL9 Vpr
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B7)
Assay type CD8 T-cell Elispot - IFNγ
Keywords supervised treatment interruptions (STI), escape, early treatment, superinfection
References Altfeld *et al.* 2002a

- An HIV+ individual given acute ARV and undergoing STI developed a strong CTL immune response, but despite this was shown to be superinfected with second B clade virus. Some epitope variants of the second infecting virus were resistant to the initial CTL response.
- The second infecting strain had the variant fpWtwlhgl. The CTL response declined over time and the response to the second variant was lower than to the first one all the time points.

HXB2 Location Vpr (34–42)
Author Location Vpr
Epitope FPRIWLHGL
Epitope name FL9
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B7)
Donor MHC A2, B44, B7, Cw5, Cw7
Country United States
Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, escape, characterizing CD8+ T cells, viral fitness and reversion
References Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host.The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- One escape mutation, at position 8, FPRIWLHdL was found not to correspond to the most polymorphic residue in the epitope.

Immunogen HIV-1 infection
Species (MHC) human (B7)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins

References Altfeld *et al.* 2006
- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

HXB2 Location Vpr (34–42)

Epitope FPRPWLHGL
Epitope name Vpr1125
Subtype C
Immunogen HIV-1 infection, computer prediction
Species (MHC) human (B7)
Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords binding affinity, computational epitope prediction, HLA associated polymorphism
References De Groot *et al.* 2008
- 45 highly conserved, putative HLA-B7-restricted epitopes were identified with EpiMatrix and evaluated for HLA binding and ELISpot assays. 40 epitopes were functional and 18 of them are novel, 7 were not previously described as HLA-B7-restricted.
- Epitope FPRPWLHGL elicits IFN-gamma ELISpot responses in 3/7 subjects; and bound HLA-B7 with high affinities in soluble and cell-based assays. Previously published HLA restrictions of this epitope include A*0204, A*0201 (LANL database).

HXB2 Location Vpr (34–42)
Author Location
Epitope FPRIWLHGL
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002
- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Epitope FPRPWLHSL
Epitope name FL9
Subtype C
Immunogen HIV-1 infection
Species (MHC) human
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Other
Keywords supertype, cross-presentation by different HLA, TCR usage
References Leslie *et al.* 2006
- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related

but different HLA alelles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction
- Statistically significant associations between numbers of HLA-B8101, -0702 and -B4201 expressing subjects and epitope FPRPWLHSL were found.
- Only B*0702 was associated with variation within this epitope, FL9.

Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

Keywords acute/early infection, early-expressed proteins
References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

Keywords optimal epitope
References Altfeld *et al.* 2001c; Llano *et al.* 2009

- C. Brander notes this is an A*0201 epitope.

HXB2 Location Vpr (59–67)
Author Location Vpr (58–66 SF2)
Epitope AIIRILQQL
Epitope name AL9
Immunogen HIV-1 infection
Species (MHC) human (A*0201)
Keywords acute/early infection
References Altfeld *et al.* 2001a

- CTL responses against HIV-1 Vpr, Vpu, and Vif were analyzed in multiple HIV-1-infected individuals.
- This epitope was recognized by 8/24 individuals expressing A*0201 allele.
- Epitope is located within a highly conserved alpha helix in Vpr.
- Individuals with long-term nonprogressive and treated chronic HIV-1 infection targeted Vpr more frequently than individuals with treated acute infection.
- Vpr is a frequent target of HIV-1 specific CD8+ T-cells – a response was detected in 45% of individuals tested and Vpr and p17 were the most preferentially targeted proteins per unit length by CD8+ T-cells.
- The A2 epitopes Vpr AIIRLLQQL and p17 SLYNTVATL do not account for the dominance of Vpr and p17, the result holds even when HLA-A2+ individuals are excluded.

HXB2 Location Vpr (59–67)
Author Location Vpr (59–)
Epitope AIIRILQQL
Epitope name Vpr-59
Immunogen HIV-1 infection
Species (MHC) human (A*0201)
Keywords binding affinity, subtype comparisons, supertype, computational epitope prediction, immunodominance
References Altfeld *et al.* 2001c

- HIV was scanned for all peptides which carried the A2-supermotif pattern conserved in more than 50% of B clade sequences – 233 peptides met this criteria, and 30 of these bound to HLA-A*0201 – 20/30 bound to at least 3/5 of HLA-A2 supertype alleles tested.
- Three additional previously described HLA-A2 epitopes were added to the set of 20, and 18/22 chronically infected HLA-A2 individuals had CTL that recognized at least one of the 23 peptides (median of 2 and maximum of 6), while 6/12 acute infected individuals recognized at least 1 (median of 1 and maximum of 2)
- AIIRILQQL binds to four HLA-A2 supertype alleles: A*0203, A*0201, A*0206 and A*6802 (highest affinity), but not A*0202.
- 5/22 individuals with chronic HIV-1 infection recognized this epitope, but with low magnitude responses in ELISPOT.
- 2/12 HLA-A2 patients with acute HIV-1 infection responded strongly to this peptide, but during chronic infection SL9 and Gag-386 tended to be immunodominant while Vpr-59 was weak and sub-dominant.
- One of the the acutely infected individuals, AC13, was HLA A*0201/68 B44/14 and also had a strong acute response to gp41 epitope SV10 SLLNATDIAV.
- This peptide was shown to be properly processed and presented in TAP-competent B-cell lines *in vitro*.

Assay type CD8 T-cell Elispot - IFNγ
Keywords binding affinity, acute/early infection, early-expressed proteins
References Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

Assay type CD8 T-cell Elispot - IFNγ
Keywords HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism
References Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A*0201 restricted eptiope, AIIRILQQL, was mutated to AI(L)RILQQL in the daughter D2 isolate.

Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Immunogen HIV-1 infection
Species (MHC) human (B53)
Assay type Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords class I down-regulation by Nef
References Bobbitt *et al.* 2003

- Nef, through Nef-mediated MHC-1 down-regulation, is not the only viral protein to influence levels of HIV-specific CTL recognition. The Rev L60F mutation, a common natural variant, can decrease CTL recognition of late gene products. The Rev mutation impacts the early to late gene switch, reducing late gene product production (Gag, Pol, Env, Vpu, Vpr and Vif), while increasing Nef production, both of which reduce the impact CTL recognition of late gene products. As expected, Rev L60F rendered HIV infected cells more resistant to CTL that recognized epitopes from the late proteins Env and Gag. Gag expression is reduced more than Env, and Gag-specific CTL were more profoundly affected. Conversely CTL against an epitope in an early gene product, Tat, were more effeciently recognized when infected with viruses carrying the Rev L60F mutation.

CTL CD8+

- Patients in the asymptomic phase with active immune responses had more CTL resistant viruses, with lower Rev activity, lower Gag expression and greater resistance to Gag-specific CTL killing, while viruses isolated from people with AIDS were more sensitive to CTL killing.

Epitope WPVDPRLEPW
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Positions 5 and 7 in the epitope had potentially experienced positive selection. PVDPRLdPW, PVDPsLEPW and PVDPkLEPW escape variants were found.

Keywords dynamics, acute/early infection, characterizing CD8+ T cells
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape muations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

Keywords HLA associated polymorphism
References Rousseau *et al.* 2008

- 3 phylogenetic correction methods—MLL (maximum likelihood character state analysis followed by likelihood ratio test), MLF (maximum likelihood character state analysis followed by Fisher test), and parsimony character state analysis were used to identify points in the HIV-1 subtype C proteome that conferred susceptibility or resistance to CTLs. Associations of HLA-epitope combinations that were inferred to be susceptible or resistant were organized into immunological sets that would help identify the best residues and genes as candidates for vaccines. While all proteins were interrogated, Gag, Pol, Env and Nef were focused upon. Amino acid changes were evaluated for association with plasma viral load.
- Proteome maps may be seen at http://www.hiv.lanl.gov/content/immunology/hlatem/study5/index.html with information showing single or multiple sites involving escape and reversion.
- HLA- B and -C alleles associated more with aa changes than HLA-A, suggesting that the former two are more important in driving viral evolution.
- The ratio of susceptible to resistant residues in HIV proteins was in descending order, Vpr>Gag>Rev>Pol>Nef>Vif>Tat>Env>Vpu, showing that epitopes from the earlier proteins are more conserved owing to viral fitness cost upon mutation.

References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, PKTACTNCY, is similar to human protein Zinc finger protein, sequence SQPKsACgNCY.

Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords HAART, ART, escape, viral fitness and reversion
References Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rates for this epitope, NCYCKKCCF, were found to be 0.047 and 0.006/day (optimistic escape rates = 0.051 and 0.013), with SE of 0.054 and 0.004 respectively.
- In the first subject, 3 mutations in this Tat epitope (N24K, N24K+K29R, N24K+K29Q) were all shown to confer escape. In the second subject, peptide recognition was not tested, but by analogy with another patient it was suggested that a N to K mutation at position 1 of the epitope Tat 24-32 conferred escape. An additional N to T mutation at position 1 was also considered likely to be an escape mutation.

References Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- A early response to this peptide KCCFHCQVCFTTKGL was detected that waned prior to superinfection. The embedded epitope and HLA presenting molecule were not resolved. The initial and superinfecting strains had different versions of the peptide, oCCFHCQVCFiTKGL and KCClHCQVCFTrKGL respectively.

Keywords acute/early infection, early treatment
References Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- Two individuals recognized this epitope both presented by Cw*1203.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.

References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- Position 3 in the epitope had potentially experienced positive selection. CClHCQVC and CCFHCQsC escape variants were found.

Keywords vaccine-induced epitopes
References Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromized by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

Keywords computational epitope prediction, escape, acute/early infection, immune evasion
References Guillon *et al.* 2006

- A longitudinal study from primary infection to 5 years postinfection was conducted to determine Tat and Rev gene evolution. 2/4 patients showed Tat gene evolution. It was found that though Tat evolved by mostly nonsynonymous, non-random sequence changes, there was no increase in transactivating capacity or size of Tat protein. Sequence evolution occurred mostly in predicted epitopes that are MHC I restricted.
- Tat and Rev seem to evolve due to CTL pressure later in infection, after seroconversion, and possibly during viral replication.
- The predicted epitope C(l)HCQVCFI, had a variant CfHCQVCFI in the second position.

References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape muations in SUMA over time. Early in infection, three overlapping epitopes in Tat carried mutations: FHCQVCFMTK, VCFMTKGLGI, and MTKGLGISY. An M->T substitution

was evident during acute infection in the first sample, at four days of the onset of symptoms, and a rare second variant was seen at day 20 that added a K->E substitution. The M->T substitution abrogated responses to FHCQVCFtTK, VCFtTKGLGI, but not in the third epitope tTKGLGISY. By day 69 a double mutation was evident that persisted through day 435, F->L and T->K. Variants lHCQVCFMkK, VCFMkKGLGI were not recognized,and impact processing of the MkKGLGISY epitope.

Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords HAART, ART, escape, viral fitness and reversion
References Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, FHCQVCFITK, was found to be 0.066 (optimistic escape rate = 0.189) per day, with SE of 0.032.
- In this region of Tat there were 3 overlapping CTL epitopes. A T to K mutation at Tat 32 completely abolished in vitro CTL lysis against all three epitopes. In addition, an M to T mutation at Tat 31 completely abolished recognition of two of the epitopes (third not tested). Quantifying the outgrowth of both of the mutations will overestimate the efficiency of a single CTL response.

Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining
Keywords binding affinity, immunodominance
References Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, FHCQVCFTTKGLGISYGR, had an overall frequency of recognition of 16.7% - 16.9% AA, 15.4% C, 20.5% H, 9.5% WI.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A*11-restricted epitopes were recognized less frequently than other epitopes, and A*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, VCFTTKGLGI, was detected within overlapping peptides FHCQVCFTTKGLGISYGR and TKGLGISYGRKKRRQRRR.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Assay type CD8 T-cell Elispot - IFNγ, CD4 T-cell Elispot - IFNγ
Keywords rate of progression, escape
References Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses,and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant eptiopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This was one of 8 reactive epitopes found not to vary over time.

HXB2 Location Tat (39–49)

Epitope `ITKGLGISYGR`
Immunogen HIV-1 infection
Species (MHC) human (A*6801)
Assay type CD8 T-cell Elispot - IFNγ, Degranulation, CD107a and b cell surface mobilization, Other
Keywords binding affinity, epitope processing, kinetics, characterizing CD8+ T cells
References Gostick *et al.* 2007

- HLA-A*6801 was studied because of its unusual property of weak binding to CD8. Several peptide variants were followed in a CTL clone grown from an A*68 expressing patient who responded to his autologous "index" peptide iTKgLGISYGR. His founder epitope was suggested to be TTKALGISYGR, the "reference" sequence, with variants ITKaLGISYGR and tTKGLGISYGR. The reference sequence TTKALGISYGR is a better agonist in cytokine and degranulation assays than the index peptide iTKgLGISYGR. Surface plasmon resonance shows that both index and reference peptides bind soluble TCR within normal ranges. A mutant HLA-A68 that increases CD8 interaction was found to recognize CTL at lower peptide concentrations and increase cytokine production (IFN-g, MIP-1b, RANTES). However its pattern of variant recognition was not changed. Thus "normalization" of HLA-A*6801 interaction with CD8 does not induce non-specific activation, but does enhance agonist peptide recognition and immune response.

Epitope ITKGLGISYGR
Epitope name A68-IR11(Tat)
Immunogen HIV-1 infection
Species (MHC) human (A68)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Epitope TKGLGISY
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B*1503)
Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, rate of progression, immunodominance, characterizing CD8+ T cells
References Frahm *et al.* 2006

- CTL responses restricted by HLA-B*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects inspite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominanat CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.
- TKGLGISY of clade B is a potential HLA-B*1503-restricted epitope, with epitope qTKGLGISY found in clade C.

Epitope TKALGISYGR
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

References Gavioli *et al.* 2004

- HIV-1 Tat protein modulates proteasome composition and activity in B and T cells that either express Tat or are treated with exogenous biologically active Tat protein. This results in modification of Ag processing where presentation of immunodominant EBV epitopes is decreased and presentation of subdominant epitopes is increased. The authors suggest that the immunomodulatory effects of endogenous and exogenous Tat may be beneficial in terms of expanding stimulation of responses to subdominant epitopes, and may be useful as an adjuvant.

References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, EELLKTVRL, is similar to human protein nucleolar RNA associated protein, sequence EELLKeVRL, and a human protein, sequence LLKTVRLlRLL.

Epitope KTGRLIKLLY
Epitope name KY10
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B57)
Donor MHC A1, A3, B57, B7, Cw6, Cw7
Country United States
Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, escape, characterizing CD8+ T cells, viral fitness and reversion
References Allen *et al.* 2005a

CTL CD8+

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host.The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- One escape mutation, at position 8, ktgrlikLly, was found in the most polymorphic residue in the epitope. One escape mutation, at position 5, ktgrFiklly was found not to correspond to the most polymorphic residue in the epitope.

Epitope KAVRLIKFLY
Immunogen HIV-1 infection
Species (MHC) human (B*5801, B57)
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords responses in children, mother-to-infant transmission
References Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.
- This epitope was recognized less frequently in children than in adults.

Epitope KTVRLIKFLY
Subtype B, C
Immunogen HIV-1 infection
Species (MHC) human (B57, B58, B63)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, cross-presentation by different HLA, optimal epitope
References Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- This epitope was recognized by 20% of B63-positive subjects and 12% of B57/58-positive subjects.

Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Epitope AVRIIKIL/M
Subtype C
Immunogen HIV-1 infection
Species (MHC) human
Keywords HLA associated polymorphism
References Rousseau *et al.* 2008

- 3 phylogenetic correction methods—MLL (maximum likelihood character state analysis followed by likelihood ratio test), MLF (maximum likelihood character state analysis followed by Fisher test), and parsimony character state analysis were used to identify points in the HIV-1 subtype C proteome that conferred susceptibility or resistance to CTLs. Associations of HLA-epitope combinations that were inferred to be susceptible or resistant were organized into immunological sets that would help identify the best residues and genes as candidates for vaccines. While all proteins were interrogated, Gag, Pol, Env and Nef were focused upon. Amino acid changes were evaluated for association with plasma viral load.
- Proteome maps may be seen at `http://www.hiv.lanl.gov/content/immunology/hlatem/study5/index.html` with information showing single or multiple sites involving escape and reversion.
- HLA- B and -C alleles associated more with aa changes than HLA-A, suggesting that the former two are more important in driving viral evolution.
- The ratio of susceptible to resistant residues in HIV proteins was in descending order, Vpr>Gag>Rev>Pol>Nef>Vif>Tat>Env>Vpu, showing that epitopes from the earlier proteins are more conserved owing to viral fitness cost upon mutation.
- This Rev HLA A*3001-restricted epitope, AVRIIKIL/M was susceptible at R3. Variants AVkIIKIL/M and AVqIIKIL/M were resistant to CTL response, but associated with lower viral loads. This epitope is 1 of 7 that suggest a fitness cost to immune escape.

Epitope TVRLIKFLY
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A*03)
Donor MHC A*03, A*24, B*35, B*40
Country United States
Assay type CD8 T-cell Elispot - IFNγ
Keywords superinfection, characterizing CD8+ T cells
References Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- The response to this epitope, TVRLIKFLY, was present only after superinfection. The epitope from the first infecting strain had the substitutions tvKIikfly relative to the test peptide, while the second strain shared the sequence TVRLIKFLY.

Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords escape, acute/early infection, characterizing CD8+ T cells
References Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient. In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.
- The second donor in the study shares A*0101 and B*0801 with his partner. The escape variant iserilstF was transmitted, and it abrogates binding to A*0101.

- Cross-clade CTL epitope recognition was tested for functional responses by CTL suppression using endogenously derived cell-surface epitopes rather than supraphysiologic exogenously added peptide epitopes. Functional avidity was actually diminished in non-autologous clade epitopes, calling into question current methods for assessing cross-clade or standard CTL activity and therefore vaccine design.
- RL10 epitope variants used were RPAEPVPLQL for clades B/C/G, RSAEPVPLQL for clade A1, RPTEPVPLQL for clades A2/F2, RSEEPVPLQL for clade D, and RPEEPVPLQL for clade F1. Clade B-elicited CTLs recognized epitopes from all other clades when tested by Cr-release. Suppression of HIV replication however, as well as functional avidity were reduced for different clade consensus epitope sequences.

- Standard assays like ELISpot, ICS and tetramer staining do not measure antiviral activity of HIV-infected CTLs, but use exogenous synthetic peptides on uninfected cells, or HLA tetramers. Similarly, functional avidity assesses CTL activity against uninfected target cells. Here functional avidity is compared to the efficiency of actual infected cells' recognition and killing, revealing a sharp threshold between CTL immune antiviral activity and lack of infected cell recognition.
- As previously shown, epitopes and their variants spanned orders of magnitude of SD50. Likewise, CTL clearance of infected cells varied from 0 to 100% with epitope sequence variation. Moreover, direct suppression of HIV-1 replication by CTLs also varied with epitope variant.
- When killing efficiency (KE) using virus-infected cells was compared to functional avidity using synthetic peptides, there was a narrow threshold separating maximal killing from almost none. Since different SL9-specific clones had similar KEs, which were vastly different from RL10-specific CTL KEs, it was obvious that KEs varied with epitope sequence too. Finally, a strong correlation between KE and inhibition of viral replication was also seen.
- This epitope, RPAEPVPLQL, showed marked differences in its functional avidity, killing efficiency, as well as inhibition of viral replication when compared to its variants RsAEPVPLQL, RPtEPVPLQL, RPeEPVPLQL, RPAqPVPLQL, RPAEPVPLhL, RPAEPVPfQL, RPvEPVPLQL, RPeEPVPfQL, RPeEPVPLpL, RPAEPVPfhL, RPtEPVPfQL, RPtEPVPLeL, RPqEPVPLlL and RPtEPVPfhL.

References Honeyborne *et al.* 2007

- To determine whether HLA-B*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.
- An HLA-B*13-restricted epitope was found within the above overlapping peptide sequences, but the optimal epitope was not confirmed.

- Molecularly cloned primary NSI macrophage tropic strain 2.1 and SI non-macrophage tropic strain 1.2 were isolated from study participant ACH320 and use to infect irradiated XID mice that had been reconstituted with human PBMC from B14+ seronegative donors – results indicate CTL may favor selective outgrowth of macrophage tropic strains.
- The CTL clone TCC108 specific for SAEPVPLQL, previously described by van Baalen 1997, and van Baalen 1998, was stimulated *in vitro* and given to the mice to apply specific CTL pressure.
- The macrophage-tropic HIV-1 strain #2.1 escaped CTL pressure more efficiently (7/14 animals) than its non-macrophage-tropic counterpart #1.2(SI) – the latter isolate was suppressed in 13/14 animals – macrophage may serve as a CTL sanctuary and reduced pressure on macrophage tropic HIV strains may allow additional replication to assist with acquisition of escape.
- Specific HIV-1 variants selectively induced by TCC108 were for strain 1.2: SEEPVPLQL, and for strain 2.1: SAEHVPLQL, SAESVPLQL, SVEPVPLQL, SLEPVPLQL, SAEPVPFQL, and SAEPVPFQL.

CTL CD8+

- Tat, Rev and Nef are the first HIV proteins expressed upon acute infection of T-cells (< 6 hours), and RT is not expressed until after 24 hours. The B14-restricted Rev-SAEPVPLQL specific CD8 T-cell clone TCC108, and the B57-restricted RT-IVLPEKDSW specific CD8 T-cell clone TCL1C11 were co-incubated with CD4+ cultures innoculated with HIV-1 at low MOI. Co-incubation with the Rev-specific CTL resulted in two logs less HIV-1 production in ten days of culture. When the RT epitope was cloned into the Nef gene of the infecting strain, another early expressed protein, it proved as effective as the Rev epitope at inhibiting viral production. A mathematical model of CTL-target interactions suggest early proteins are important for vaccine design.

References Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Keywords assay standardization/improvement, optimal epitope
References Wang *et al.* 2007c

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A*11-restricted epitopes were recognized less frequently than other epitopes, and A*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, LQLPPLERL, was detected within overlapping peptide PLQLPPLERLTLDCNED.

HXB2 Location Rev (73–81)
Author Location Rev (73–)
Epitope LQLPPIERL
Epitope name Rev73
Immunogen HIV-1 infection, vaccine
Vector/Type: peptide *HIV component:* Rev
Adjuvant: Incomplete Freund's Adjuvant (IFA)
Species (MHC) human, transgenic mouse (A2)
Keywords binding affinity, subtype comparisons, computational epitope prediction
References Corbet *et al.* 2003

- HLA-A2-restricted HIV-1 CTL epitopes were computationally predicted. Binding affinities for HLA-A*0204, immunogenicity in HLA-A*0201 transgenic mice, and responses to the peptides in 17 HIV-1 infected patients were tested. 31 novel conserved A2 epitopes were detected. An average of 4 epitopes were recognized per patient.
- This peptide was a good A2 binder, and induced CTL responses in mice. Responses to the peptide were not detected in 17 HIV+ HLA-A2 subjects.

Epitope QLPPLERLT
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A2)
Donor MHC A2, B13, B41
Country France
Assay type Other
Keywords computational epitope prediction, escape, acute/early infection, immune evasion
References Guillon *et al.* 2006

- A longitudinal study from primary infection to 5 years postinfection was conducted to determine Tat and Rev gene evolution. 2/4 patients showed Tat gene evolution. It was found that though Tat evolved by mostly nonsynonymous, non-random sequence changes, there was no increase in transactivating capacity or size of Tat protein. Sequence evolution occurred mostly in predicted epitopes that are MHC I restricted.
- Tat and Rev seem to evolve due to CTL pressure later in infection, after seroconversion, and possibly during viral replication.
- No variants of epitope QLPPLERLT were found in the subjects under study.

HXB2 Location Rev (75–83)
Author Location
Epitope LPPLERLTL
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Keywords epitope processing, escape
References Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

Assay type Flow cytometric T-cell cytokine assay
Keywords rate of progression, escape, acute/early infection
References Fomsgaard *et al.* 2008

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.
- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Rev epitope ILVESPAVL, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients. DK1 had variant sequence IpVESPtVL.

Epitope `LAIVALVVA`
Subtype B
Immunogen HIV-1 infection, peptide-HLA interaction
Species (MHC) human
Assay type CD8 T-cell Elispot - IFNγ
Keywords immunodominance
References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, LAIVALVVA, is similar to human protein Trypsin-domain protein, sequence alVALVVApL, and human small inducible cytokine 28 protein, sequence LAIVALaV.

Assay type CD8 T-cell Elispot - IFNγ, Flow cytometric T-cell cytokine assay
Keywords vaccine-induced epitopes
References Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromized by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

Epitope name Vpu 66
Immunogen HIV-1 infection
Species (MHC) human
Country Denmark
Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords variant cross-recognition or cross-neutralization
References Thorn *et al.* 2007

- 11 HLA-A2+ (A*0201, A*0220, A*0234 or A*0236), patients' HIV were sequenced. Of 28 epitopes studied, most were conserved and elicited a subdominant CTL response. 9 epitopes in 7 proteins showed T-cell cross reaction. These epitopes were optimized to induce more immunogenic but cross-reacting responses.

CTL CD8+

- Epitopes in Gag, Pol, Env, Nef were more conserved than epitopes in shorter proteins Vpu, Vif, Vpr and Rev. Most natural epitopes were untargeted or targeted by 1 or 2 patients.
- Vpu 66 ALVEMGHHA was found in 5 patients, being most conserved of Vpu epitopes. It was poorly immunogenic however, with no HLA-A2+ subjects responding to it and recognition by only 1 HLA-A2- patient.
- Anchor optimization to the Vpu66(9Vmod) variant, ALVEMGHHv, induced a very strong immune response, cross-reacting to natural Vpu66(9A).
- One patient reactive to Vpu 66 was not responsive as measured by IC-IFNgamma-FACS but by IC-TNFalpha and IC-IL-2-FACS.

Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, immunodominance
References Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher interclade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm et al. [J. Virol. 78:2187-2200 (2004)].
- This peptide, aaeNLWVTVYYGVPVWK differs from the consensus C sequence vggNLWVTVYYGVPVWK at 3 amino acid positions, i.e. by 17.6%.

Keywords HAART, ART, immunodominance, TCR usage, memory cells
References Weekes *et al.* 2006

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintainance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

Keywords rate of progression, escape
References Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses,and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant eptiopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This was one of 8 reactive peptides found not to vary over time. It was one of four epitopes that were not precisely defined.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords dynamics, immunodominance, escape, acute/early infection, kinetics, characterizing CD8+ T cells, viral fitness and reversion
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- This was the immunodominant response in acute infection in WEAU, and there was rapid escape in the epitope AENLWVTVY, with three variants observed by day 30 from the onset of symptoms. Additional mutations continued to develop, so that there were 9 different forms observed through the course of sampling. The variants all conferred different levels of reduction in CTL response, double mutations or anchor mutations tended to cause the greatest reduction: AaNLWVTaY, tNkWVTVY, AgNLWVTVY, AkNLWVTVY, although the double mutant tENLWVTiY elicted a very strong CTL response, suggesting it might not be an escape form.

- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.
- The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
- Previously described and newly defined optimal epitopes were tested for CTL response.
- Number of HLA-B44+ individuals that had a CTL response to this epitope broken down by group: 1/8 group 1, 2/3 group 2, and 3/4 group 3.

Epitope AENLWVTVY
Immunogen HIV-1 infection
Species (MHC) human (B44)
Keywords epitope processing
References Cao *et al.* 2002

- AC2 is a B44 restricted CTL clone that recognizes AENLWVTVY.
- CTL could be activated by a fusion protein of an HIV protein and anthrax lethal factor (LFn-HIV) that promotes antigen presenting cell uptake of exogenous protein and allows processing through the MHC class I pathway. This strategy for CTL detection could allow antigen presentation without generation of cells by the standard methods of using live viral vectors carrying a protein, or by loading the cells with peptides and by-passing processing.

Keywords assay standardization/improvement, memory cells, characterizing CD8+ T cells
References Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords binding affinity, immunodominance, optimal epitope
References Bihl *et al.* 2006

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope AENLWVTVY elicited a magnitude of response of 160 SFC with a functional avidity of 5nM.

Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords HAART, ART, escape, viral fitness and reversion
References Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, AENLWVTVY, was found to be 0.048/day (upper bound on rate of escape = 0.053), with SE of 0.022.
- Mutations at position 30 (E30G and E30A) were shown to confer escape.

CTL CD8+

Species (MHC) human (B44)
Keywords immunodominance, escape
References Borrow *et al.* 1997; Borrow & Shaw 1998; Goulder *et al.* 1997a

- Two CTL lines from the patient WEAU were studied – one had an optimal peptide of (A)AENLWVTVYY, and the other (A)AENLWVTVY, and both responded equally well with one or two N-term Alanines.
- Rapidly post-infection, a strong immunodominant response was observed against this epitope.
- The naturally occurring forms of the peptide found in WEAU were tested as targets for early WEAU CTLs – the form TENLWVTVY was as reactive as the wild type AENLWVTVY – but the forms AKNLWVTVY, AGNLWVTVY, AANLWVTVY did not serve as targets.
- The glutamic acid in the second position is a B44 anchor residue.
- Goulder *et al.* [1997a] and Borrow & Shaw [1998] are reviews of immune escape that summarizes this study in the context of CTL escape to fixation.

References Paris *et al.* 2004

- 21% (40/187) of Thai adults that recieved ALVAC-HIV with or without gp120 or oligomeric gp160 had a CD8+ T-cell response. HLA-B44 was positively associated with CTL responses, and A33 had a borderline significance association with response. A33/B44/DRB1*0701 is the most common haplotype in Thailand. B46, present in 30% of the population, was negatively associated with CTL responses, although it did not reach significance. HLA class I serotypes A11, A24, A33, B46 and B75 were the most common found in 245 Thai volunteers.
- 9/11 cases of pCTL activity to Env were in people with B44. The authors suggest some of the response may be directed at the previously mapped B44 Env epitope AENLWVTVYY in HXB2, DNLWVTVYY in their CRF01 ALAVC vaccine 92TH023. B*4403 is the most common B44 allele among Thais, while B*4402 is more common among Caucasians; a prior study had shown that B*4403 may be able to present a broader spectrum of epitopes than B*4402.

Keywords dynamics, acute/early infection, characterizing CD8+ T cells
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape muations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

Keywords HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism
References Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than interperson sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A2/A2.1 restricted epitope, KLWVTVYYGV was mutated to nwWVTVYYGV in the daughter D2 isolate.

- Telomer length is short in the CD8+ T-cell compartment of HIV-1 infected people, indicating excessive CTL activation and premature senescense. Here human telomerase RT (hTERT) transduction of HIV-1-specific CTL was used to

CTL CD8+

study the functional impact of telomerase. Telomerase expression enhanced proliferative capacity, as well as cytolytic and antiviral capabilities; cytokine production was unchanged. hTERT transduced CTLs were 10-fold more efficient in controlling HIV-1 replication in culture. Thus telomerase transduction can restore CTL mediated cytolysis, and may have therapeutic potential.
- Three polyclonal CD8+ T-cell lines derived from an HIV-1, HLA A*0201 positive patient were used in this study, including one specific for this epitope.

References Wilson *et al.* 2003

- 21 supertype-A2, -A3 and -B7-restricted epitopes predicted to be immunogenic by HLA-peptide binding motifs and phenotypic frequency in individuals were recognized by HIV-1 + subjects in ELISpot assays and shown to bind with high affinity to minimum 3 HLA-alleles of the restricting supertype. These epitopes were included in DNA vaccine EP HIV-1090 that avoided immunodominant responses and did not restrict subject immunity to predicted HLA-type when tested in mice. Transgenic mice mounted a vaccine-response similar to that induced by ELISpot assay in humans.
- Epitope VTVYYGVPVWK of the HLA-A3 supertype bound most strongly to HLA-A*1101, -A*0301 and -A*6801 and also to -A*3301 but not -A*0301. It was conserved 25% in subtype A, 95% in B, 100% in C and 75% in subtype D. 3/23 HLA-A3 supertype expressing HIV-1 + subjects mounted a positive ELISpot response to Env47.

Epitope TVYYGVPVW
Epitope name TW9
Subtype A
Immunogen HIV-1 infection
Species (MHC) human (A*03, A*11)
Country Kenya
Assay type Cytokine production, proliferation, CD8 T-cell Elispot - IFNγ
Keywords assay standardization/improvement
References McKinnon *et al.* 2007

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.
- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTs as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 4 variants of this index epitope TVYYGVPVW, TW9, were tested - TiYYGVPVW, TVYYGiPVW, TVYYGVPrW, TVYYGVPmW. This index peptide, TW9, and its variants show a high proportion of instances where IFN-gamma ELIspot and proliferation correspond well.
- TW9 has previously published restrictions to HLA-A*11, -A*03 and -B*03.

References McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. TVYYGVPVW responses were detected in 2 women who reacted to all clades tested, A, B, C, and D, and the sequence was identical in all clades.

Assay type proliferation, CD8 T-cell Elispot - IFNγ
Keywords assay standardization/improvement
References McKinnon *et al.* 2008

- To evaluate the use of IFN-gamma ELISpot and proliferation assays, the two were compared in a cohort of HIV-1-infected Kenyan sex-workers. ELISpot does not always correlate with viral load and replication or disease progression. The exclusive use of these assays makes definition of CTL response in disease incomplete, especially for memory T cells.
- Despite assaying for 24 INF-gamma and 41 proliferative responses, only 5 of these responses overlapped in the same subject. 18 peptide-epitopes including 10 epitopes and their variants were used in this study.
- TVYYGVPVW elicited proliferation responses in 3 subjects; ELISpot response in 1 subject; both proliferation and ELISpot in 1 subject.

Immunogen HIV-1 infection
Species (MHC) human (A*0301)
Keywords acute/early infection
References Wilson *et al.* 2000a

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and there was a close temporal relationship between the number of circulating HIV-specific T cells and viral load was also found.
- All three patients were B*2705, with HLA alleles: A1, A30/31, B*2705, B35; A1, A*0301, B7, B2705; and A*0201, A*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B*2705 epitope KRWIILGGLNK.
- The subject with A*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A*301-RLRPGGKKK, A*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A*0301, B7, B*2705.

- No acute response was detected to the following epitopes: A*201-ILKEPVHGV, A*301-KIRLRPGGK, A*301-AIFQSSMTK, A*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

Keywords subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance
References Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFNgamma Elispot assays after vaccination of 5 macaques. The response to the Mamu A*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

- 1100 unique full-length Env sequences were analyzed and the positive selection (PS) pressure determined. The QUASI method was used across Clades A, B, C and D, to find PS sites dispersed across Env.
- Frequency of PS sites is stable over time.
- 25% to 61% PS sites are shared between subtypes A, B, C and D, so it is inferred that immune responses are targeted against the same general regions.
- Significant correlations between PS sites and neutralizing antibody response, helper response, antibody plus CTL response are found. This suggests that the NAb response might be the driving force behind HIV-1 Env evolution.
- PS-free sites that are targeted greatly by NAb and CTL were found. Functional reasons for the lack of positive selection in such regions must exist.
- PS-site-rare regions (conserved regions of Env) were examined for PS, and epitopes located in such regions. Epitope TVYYGVPVWK, restricted by HLA-A*0301, is on a region free from positive selection. It is found in European populations and has no known association with progression to AIDS.
- Overlapping conserved NAb 4E10 epitope LWVTVYYGVPVWK was also found and thought to be protective against HIV-1.

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher interclade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm et al. [J. Virol. 78:2187-2200 (2004)].
- This peptide, TVYYGVPVWKEAtTTLF differs from the consensus C sequence TVYYGVPVWKEAkTTLF at 1 amino acid position, i.e. by 5.9%.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most

CTL CD8+

differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, TVYYGVPVWKEATTTLF, had an overall frequency of recognition of 22.7% - 25.4% AA, 19.2% C, 18.2% H, 28.6% WI. This peptide is included in a 41 aa gp120 highly reactive region to be used for vaccine design.

HXB2 Location gp160 (38–48)
Author Location gp120 (45–55)
Epitope VYYGVPVWKEA
Immunogen HIV-1 infection
Species (MHC) human (Cw7)
References Nehete *et al.* 1998a
- Three long-term non-progressors and one asymptomatic HIV+ individual were studied and found to have HLA class I C-restricted CD8+ Env-specific CTLs – Cw7 specific CTL were found against three peptides, including this one.
- HLA-C antigens are expressed on lymphoid cells to a lesser extent than either HLA-A or -B.
- HLA-C confers protection against lysis by natural killer cells and by non-MHC-restricted effector T cells and Cw7 directly governs this resistance to lysis – the authors hypothesize that pathogens that inhibit antigen expression and class I expression may particularly down regulate Cw7, thus triggering non-MHC restricted killing.

Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Keywords rate of progression, escape
References Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses,and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant eptiopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This was one of 8 reactive peptides found not to vary over time. It was one of four epitopes that were not precisely defined.

References Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to published restriction above, epitope TLFCASDAK was predicted to be restricted by HLA A*0301, A*1101, A*3101, A*3301, A*6601 and A*6801.

- 1100 unique full-length Env sequences were analyzed and the positive selection (PS) pressure determined. The QUASI method was used across Clades A, B, C and D, to find PS sites dispersed across Env.
- Frequency of PS sites is stable over time.
- 25% to 61% PS sites are shared between subtypes A, B, C and D, so it is inferred that immune responses are targeted against the same general regions.
- Significant correlations between PS sites and neutralizing antibody response, helper response, antibody plus CTL response are found. This suggests that the NAb response might be the driving force behind HIV-1 Env evolution.

CTL CD8+

- PS-free sites that are targeted greatly by NAb and CTL were found. Functional reasons for the lack of positive selection in such regions must exist.
- PS-site-rare regions (conserved regions of Env) were examined for PS, and epitopes located in such regions. Epitope TLFCASDAK, restricted by HLA-A3 is on a region free from positive selection. It is found in North American and European populations and is associated with Long Term Nonprogression to AIDS.

HXB2 Location gp160 (51–59)
Author Location Env (63–71)
Epitope TLFCASDAK
Immunogen HIV-1 infection
Species (MHC) human (A3 supertype)
Keywords supertype, rate of progression
References Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind 3/5 HLA-A3 supertype alleles (A*0301, A*1101, A*3101, A*3301 and A*6801).

Epitope LFCASDAKAY
Epitope name A24-LY10(gp120)
Immunogen HIV-1 infection
Species (MHC) human (A24)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Positions 2 and 5 in the epitope had potentially experienced positive selection. YgTEVHNVW, YdTEVHNVW, YETEaHNVW and YdTEaHNVW escape variants were found.

Assay type Chromium-release assay, Flow cytometric T-cell cytokine assay, HLA binding
Keywords binding affinity, subtype comparisons, computational epitope prediction, rate of progression, escape, variant cross-recognition or cross-neutralization
References Kawashima *et al.* 2005

- A*26 is associated with slow progression to disease and is common in Asian populations (about 20%). 31/110 HIV peptides that carried the A*2603 motif ([VTILP] at P2, [ML] at the C-terminus) bound to HLA-A*2603. Only 2 of these were epitopes and could induce specific CD8 T-cell responses in PBMC from HLA-A*2603 positive subjects.
- This epitope induced specific CD8+ T cells in chronically infected individuals with A*2603, but not A*2601.
- 5 common B clade variants were synthesized. EVHNVWATHA and EVHNiWATHA bound to A*2603 with equal affinity. EiHNVWATHA and EaHNVWATHA bound to A*2603 with reduced affinity. EmHNVWATHA and EkHNVWATHA could not bind to A*2603. A CTL clone that recognized EVHNVWATHA was able kill cells prepulsed with the 3 peptide variants that could bind to A*2602.
- EVHNVWATHA is the most common form in clades A, B, C, and E (CRF01), but EaHNiWATHA is the most common form in clade D.

References Thorn *et al.* 2007

- 11 HLA-A2+ (A*0201, A*0220, A*0234 or A*0236), patients' HIV were sequenced. Of 28 epitopes studied, most were conserved and elicited a subdominant CTL response. 9 epitopes in 7 proteins showed T-cell cross reaction. These epitopes were optimized to induce more immunogenic but cross-reacting responses.
- Epitopes in Gag, Pol, Env, Nef were more conserved than epitopes in shorter proteins Vpu, Vif, Vpr and Rev. Most natural epitopes were untargeted or targeted by 1 or 2 patients.
- Previously described Env 67(2V) epitope, NVWATHACV, was found in 10 patients but none had CTL immune responses to it. Response to the Env 67(2I)var, NiWATHACV, was however detected in one case.
- Env 67 is one of the most conserved epitopes in Env. Its variant Env 67(2V) was less targeted and immunogenic. Rare variant Env 67(2I) was more immunogenic and was also recognized by 1 in 16 HLA-A2- patients.

CTL CD8+

Assay type Flow cytometric T-cell cytokine assay
Keywords rate of progression, escape, acute/early infection
References Fomsgaard *et al.* 2008

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.
- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Env epitope NIWATHACV, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients. DK1 had sequence variant NvWATHACV.

Epitope `ACVPTDPNP`
Immunogen HIV-1 infection
Species (MHC) human
Donor MHC A*2902, B*1402
Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords HAART, ART, escape, viral fitness and reversion
References Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, ACVPTDPNP, was found to be 0.023/day, with SE of 0.016.
- Five mutations at the fifth position of Env gp41 73-81 were all shown to confer limited CTL escape.

References Wilson *et al.* 2000a
- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and a close temporal relationship between the number of circulating HIV-specific T cells and viral load.
- All three patients were B*2705, with HLA alleles: A1, A30/31, B*2705, B35; A1, A*0301, B7, B2705; and A*0201, A*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B*2705 epitope KRWIILGGLNK.
- The subject with A*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A*301-RLRPGGKKK, A*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A*0301, B7, B*2705.
- No acute response was detected to the following epitopes: A*201-ILKEPVHGV, A*301-KIRLRPGGK, A*301-AIFQSSMTK, A*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

Epitope DPNPQEVVL
Immunogen HIV-1 infection
Species (MHC) human (B35)
Keywords HAART, ART, acute/early infection
References Altfeld *et al.* 2001b

- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.
- The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
- Previously described and newly defined optimal epitopes were tested for CTL response.
- Number of HLA-B35+ individuals that had a CTL response to this epitope broken down by group: 1/2 group 1, 0/2 group 2, and 0/1 group 3.

Assay type CD8 T-cell Elispot - IFNγ
Keywords binding affinity, acute/early infection, early-expressed proteins
References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

Country South Africa
Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Assay type CD8 T-cell Elispot - IFNγ, CD4 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, escape
References Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses,and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant eptiopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody

titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This epitope was one of six epitopes found to be under positive selection for escape mutations, and was mostly replaced by an escape variant between days 66 and 369 (dpnpqeAal)and,then replaced by a new escape variant (dpnpqevPl) by day 635.

Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006
- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Keywords characterizing CD8+ T cells
References Streeck *et al.* 2008a
- T-cells were studied for exhaustion and dysfunction in chronic HIV infection. Polyfunctionality of CTL immune response to HIV-1 decreased with persistence of antigen presence over time in chronic infection. CTL exhaustion can thus be halted by reduction in viral antigen load - either by ART or through escape mutations.
- PD-1, marker for activation and apoptosis increases over time, but it decreases when epitope mutations develop. CD127 however, is not impacted by viral escape.
- Epitope DPNPQEVVL varied to DPNPQEVaL or DPsPQEVVL or DPsPQEVaL in an untreated patient. Previously published HLA-restriction for DL9 is HLA-B35.

Keywords rate of progression, escape
References Geels *et al.* 2003

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occured sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these eptiopes, but this increased over time.

Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Positions 5 and 7 in the epitope had potentially experienced positive selection. NVTEdFdMW, NVTEeFdMW and NVTEsFdMW escape variants were found.

Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords subtype comparisons, variant cross-recognition or cross-neutralization
References McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. VTEEFNMWK responses were detected in 2 women who had Env responses to all 4 clades, and clade A gave the highest responses; a VnEEFNMWK variant was in clade B and D, and the clade C Env carried VnEEFNMWe. One woman also reacted with RAIEAQQHL, the other with KNCSFNMTT.
- Both women that reacted with VTEEFNMWK carried HLA-B*5301, the only common HLA allele.

Keywords assay standardization/improvement, HAART, ART
References Chitnis *et al.* 2003

- 17 perinatally HIV-1 infected children (0.08-16 years) were evaluated for HLA-A2-restricted IFN-gamma CD8+ CTL responses against 4 immunodominant peptides that carry HLA-A2 epitopes. Two peptides were from gp120 (one at position 112, one from the V3 loop), and one each was from gp41 and Gag. 15/17 patients responded to the Gag peptide, 13/17 to the gp41 and the non-V3 gp120 peptides, and 11/17 responded to the V3 loop. 4 children recognized all 4 peptides.

Epitope KPCVKLTPLC
Immunogen HIV-1 infection
Species (MHC) human (B*07)
References Liang *et al.* 2008

- 1100 unique full-length Env sequences were analyzed and the positive selection (PS) pressure determined. The QUASI method was used across Clades A, B, C and D, to find PS sites dispersed across Env.
- Frequency of PS sites is stable over time.
- 25% to 61% PS sites are shared between subtypes A, B, C and D, so it is inferred that immune responses are targeted against the same general regions.
- Significant correlations between PS sites and neutralizing antibody response, helper response, antibody plus CTL response are found. This suggests that the NAb response might be the driving force behind HIV-1 Env evolution.
- PS-free sites that are targeted greatly by NAb and CTL were found. Functional reasons for the lack of positive selection in such regions must exist.
- PS-site-rare regions (conserved regions of Env) were examined for PS, and epitopes located in such regions. Epitope KPCVKLTPLC, restricted by HLA-B*07 is on a region free from positive selection. It is found in European populations and is associated with fast progression to AIDS.
- Conserved NAb 4E10 epitope LWVTVYYGVPVWK was also found and thought to be protective against AIDS.

Assay type Intracellular cytokine staining, Other
Keywords rate of progression, escape, immune evasion
References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- One patient developed a response to epitope KLTPLCVTL after primary infection at early chronic infection. This was one of the epitopes targeted by broad HLA-A2-restricted CTL responses.

Keywords vaccine-specific epitope characteristics, vaccine antigen design
References Bolesta *et al.* 2005

- Immunization of transgenic mice with a codon-optimized hGagp17p24-Polp51 DNA plasmid, consisting of clusters of highly conserved CTL epitopes presented by multiple MHC class I alleles, induced 2- to 5-fold higher CD8+ T-cell responses than the corresponding full-length proteins. The modified proteins had the ribosomal frameshift deleted, as well as the potentially immunosuppressive p15, and protease and integrase. This correlated with higher protection against challenge with Gag and Pol expressing recombinant vaccinia virus. Mice immunized with the hGagp17p24-Polp51 also showed an elevated level of type 1 cytokine production as well as an increased titer of p24- and RT-specific IgG2 antibody responses.
- Four A2 gag/pol epitopes were tested, and this Env A2 epitope was used as a negative control.

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.

CTL CD8+

- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Env control epitope KLTPLCVTL, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients.

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind four of the five HLA-A2 supertypes alleles (A*0201, A*0202, A*0203, A*0206 and A*6802).

Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords binding affinity, supertype, vaccine-specific epitope characteristics, cross-presentation by different HLA
References Wilson *et al.* 2003

- 21 supertype-A2, -A3 and -B7-restricted epitopes predicted to be immunogenic by HLA-peptide binding motifs and phenotypic frequency in individuals were recognized by HIV-1 + subjects in ELISpot assays and shown to bind with high affinity to minimum 3 HLA-alleles of the restricting supertype. These epitopes were included in DNA vaccine EP HIV-1090 that avoided immunodominant responses and did not restrict subject immunity to predicted HLA-type when tested in mice. Transgenic mice mounted a vaccine-response similar to that induced by ELISpot assay in humans.
- Epitope KLTPLCVTL of the HLA-A2 supertype bound most strongly to HLA-A*0203, -A*0201, -A*0202 and -A*0206, but not to -A*6802. It was conserved 75% in subtype A, 95% in B, 88% in C and 95% in subtype D. 5/22 HLA-A2 supertype expressing HIV-1 + subjects mounted a positive ELISpot response to Env134.

- 2 dual promoter candidate vaccines were constructed: ADVAX-I containing env and gag; ADVAX-II containing pol and nef-tat. The combined vaccine, ADVAX, showed equal immunogenicity in mice to single-gene plasmid vaccines, and elicited dose-dependent T-cell responses. Sequences were based on the Yunnanese subtype C/B' recombinant form of HIV-1.
- Both vaccine components induced dose-dependent IFN-gamma responses to epitope Env T-I
- IFN-gamma response was also elicited by 2 CD4 epitope-containing 20mers.

Keywords subtype comparisons, variant cross-recognition or cross-neutralization
References McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. VTEEFNMWK responses were detected in 2 women who had Env responses to all 4 clades, and clade A gave the highest responses; a VnEEFNMWK variant was in clade B and D, and the clade C Env carried VnEEFNMWe. One woman also reacted with RAIEAQQHL, the other one with KNCSFNMTT. KNCSFNMTT was identical in clades A and C, while clade B carried KNCSFNMis, clade D carried KNiSFNMTT.

Epitope NCSFNISTSI
Immunogen HIV-1 infection
Species (MHC) human (Cw*08)
Keywords epitope processing
References Ferris *et al.* 1999

- Recognized by CTL clone LWF A5, isolated from a lab worker exposed to HIV-1 in 1985.
- The processing of this epitope is TAP1/2-dependent, as are most Env epitopes, and it contains two N-linked glycosylation sites that are glycosylated in Env.
- Only peptide that has been deglycosylated, a process that changes asparagine (N) to aspartic acid (D) was recognized: the aspartic acid at position 5 was critical, position 1 could be either D or N.
- This peptide also contains a Cys involved in a disulfide linkage but reducing conditions did not effect recognition by CTL clone LWF A5.
- The HIV-1 Env epitopes are typically processed by a TAP1/2 dependent mechanism, which involves cotranslational translocation into the ER, glycosylation, export back into the cytosol, and deglycosylation for processing, and retransport into the ER for the association with class I molecules.
- The particular pathway of generating an epitope may have an impact on the presentation of that epitope, quantitatively as well as qualitatively.

Keywords computational epitope prediction
References Schellens *et al.* 2008

- Peptide prediction programs based on MHC binding, proteasomal cleavage and TAP transport were applied to select novel epitopes absent from the Los Alamos HIV database. 22 novel epitopes were tested by IFN-gamma ELISpot and 19 (11 HLA-B27 restricted, 8 HLA-B57 restricted) induced strong positive responses.
- Magnitude of response generated was similar to that of previously identified epitopes, but the number of individuals responding was lower. This could be explained by less stringent HLA-typing of subjects and perhaps high sequence variability within these novel epitopes.
- IY9, IRDKVQKEY, is a novel HLA-B27-restricted epitope that elicits a CTL IFN-gamma response in the same range as Los Alamos database peptides.

References Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, SYKLTSCNTSVITQACPKV, was found to be 0.005/day, with SE of 0.001.
- In the subject studied, the monotonic outgrowth of a Q199K mutation in Env gp41 was observed over a period of 1,028 days.

Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining
Keywords binding affinity, immunodominance
References Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors infuencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly. The virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, YRLISCNTSVITQACPKV, had an overall frequency of recognition of 15.3% - 11.9% AA, 23.1% C, 18.2% H, 9.5% WI.

References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

Keywords rate of progression, escape
References Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses,and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant eptiopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This was one of 8 reactive epitopes found not to vary over time.

References Fukada *et al.* 2002

- Counterparts for eight known clade B HLA A*1101 epitopes were generated for clade E (CRF01). Three epitopes, identical among clade A-E, were cross-reactive and recognized by clade E infected individuals. The clade E and B analogs to three more HLA A*1101 epitopes was recognized in a clade specific manner. Two other HLA A*1101 clade B defined epitopes were found not to have stimulated a response in clade E infected individuals.
- SVITQACPK was found to elicit clade-specific responses in clade B (SVITQACPK is most common, sAitqacpk is most common variant in clade A, C and D) and clade E (saiKqacpk is most common). SVITQACPK was recognized by CTL from 3/5 B clade infected Japanese subjects, and aiKqacpk by CTL from 0/7 E clade infected Thai subjects, so this seems to be a B clade exclusive epitope.
- The binding of the three variant peptides to HLA A*1101 was comparable, implicating TCR interaction differences.

- A vaccine study with B clade Envs in mice was unertaken to assess a subtype-specificity of responses. Four T-cell hybridomas responsive to subtype B envelope proteins were tested against 20 different subtype B envelope proteins and a protein each from subtypes A, C and D. IL-2 production was measured.
- No consistent correlation was found between T cell specificity towards epitopes from a certain (B) subtype or lack of specificity towards other (A, C, D) subtype.
- Not only did T-cell specificity not vary with subtype, but pairwise sequence comparisons of HIV gp120 envelope sequences showed that some US-derived sequences were more similar to sequences from distant countries than to each other.
- Changes in core epitopes, flanking and distant regions, all affected responsiveness of the hybridomas to different subtype Env epitopes, showing that it is not only core changes that can eliminate T cell reactivity to an epitope.
- The above findings were substantiated by database analyses showing that epitope distributions are not necessarily dictated by subtype.
- This paper lists several variants of the epitope above, ITQACPKVSFEPIPI.

- Peptide 740.18: Almost all CD8+ T cells are CD28+ at birth, and the proportion of CD28-CD8+ cells increases with age – this study examines the contribution of CD8+CD28- cells to CTL memory pools for CTL clones specific for two persistent human viruses, CMV and HIV – clones were found to be similarly distributed the CD28 depleted cell population.
- HIV CTL responses to 3 Env and 2 Gag peptides were studied.
- The clonal composition of the TCR Vβ responses were studied and was found to be highly focused, with one TCR beta-chain sequence tending to dominate the peptide-specific response – clones to this epitope were Vβ13.1.

Epitope TQACPKVSFEPIPIHYCAPA
Epitope name Peptide 740.18
Immunogen HIV-1 infection
Species (MHC) human
Donor MHC A11, A29, B44, B8
Country United Kingdom
Assay type Flow cytometric T-cell cytokine assay, Other
Keywords HAART, ART, immunodominance, TCR usage, memory cells
References Weekes *et al.* 2006
- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintainance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords binding affinity, supertype, vaccine-specific epitope characteristics, cross-presentation by different HLA
References Wilson *et al.* 2003

- 21 supertype-A2, -A3 and -B7-restricted epitopes predicted to be immunogenic by HLA-peptide binding motifs and phenotypic frequency in individuals were recognized by HIV-1 + subjects in ELISpot assays and shown to bind with high affinity to minimum 3 HLA-alleles of the restricting supertype. These epitopes were included in DNA vaccine EP HIV-1090 that avoided immunodominant responses and did not restrict subject immunity to predicted HLA-type when tested in mice. Transgenic mice mounted a vaccine-response similar to that induced by ELISpot assay in humans.
- Epitope CPKVSFEPI of the HLA-B7 supertype bound most strongly to HLA-B*5401, -B*0702 and -B*5101 and also to -B*5301 and -B*3501. It was conserved 75% in subtype A, 79% in B, 50% in subtype D. 3/16 HLA-B7 supertype expressing HIV-1 + subjects mounted a positive ELISpot response to Env250.

Species (MHC) mouse
Assay type Cytokine production
Keywords subtype comparisons, immunodominance
References Brown *et al.* 2006

- A vaccine study with B clade Envs in mice was unertaken to assess a subtype-specificity of responses. Four T-cell hybridomas responsive to subtype B envelope proteins were tested against 20 different subtype B envelope proteins and a protein each from subtypes A, C and D. IL-2 production was measured.
- No consistent correlation was found between T cell specificity towards epitopes from a certain (B) subtype or lack of specificity towards other (A, C, D) subtype.
- Not only did T-cell specificity not vary with subtype, but pairwise sequence comparisons of gp120 envelope sequences showed that some US-derived sequences were more similar to sequences from distant countries than to each other.
- Changes in core epitopes, flanking and distant regions, all affected responsiveness of the hybridomas to different subtype Env epitopes, showing that it is not only core changes that can eliminate T cell reactivity to an epitope.
- The above findings were substantiated by database analyses showing that epitope distributions are not necessarily dictated by subtype.
- This paper lists several variants of the epitope above, PKVSFEPIPIHYCAP.

Keywords dynamics, immunodominance, escape, acute/early infection, characterizing CD8+ T cells, viral fitness and reversion
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined, WEAU and BORI, had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape. This epitope was recognized in both patients.
- The patient BORI had high viral loads and rapid CD4 decline. BORI mounted 8 detected responses. BORI did not control viral replication well, and escape mutations occurred early and in most epitopes, 6/7 that were precisely identified. The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- Four escape variants to the SFEPIPIHY epitope were found in the patient BORI. SFdPIPIHY came up first, at day 55 from onset of symptoms, and caused a reduced cytotoxic response. By day 218, two rare forms were found, SIEPIPIHf and SiEPIPIHf. By day 556, only tFEPIPIHY was found. The weakest response was detected in the double mutant,SiEPIPIHf, yet tFEPIPIHY was the form that persisted.
- In WEAU, a minor variant, SsEPIPIHY was present at day 41. The SIEPIPIHf variant first came up day 136, gave a reduced CTL response, and then came to be the dominant form. Other variants were SFEPIPInY and SFEPIPIdf.

References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- Two subjects recognized this epitope during primary infection, both in the context of A29.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

References Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimates of escape rate for this epitope, SFEPIPIHY, were found to be 0.072 and 0.041/day (optimistic escape rate = 0.13), with SEs of 0.041 and 0.005 respectively, in 2 subjects.
- In the first subject, rapid loss of wild type at this epitope (primarily due to a E211D mutation) was observed. In the second subject, a Y217F mutation grew out over time.

References Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromized by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was contained in the vaccine, the vaccinated patient recognized it after infection.

Epitope `PIPIHYCAPAGFAILKCNNK`
Immunogen HIV-1 infection
Species (MHC) human (A2)
Keywords TCR usage
References Weekes *et al.* 1999b

- Peptide 740.19: Almost all CD8+ T cells are CD28+ at birth, and the proportion of CD28-CD8+ cells increases with age – this study examines the contribution of CD8+CD28- cells to CTL memory pools for CTL clones specific for two persistent human viruses, CMV and HIV – clones were found to be similarly distributed in the CD28 depleted cell population.
- HIV CTL responses to 3 Env and 2 Gag peptides were studied.
- The clonal composition of the TCR Vβ responses was studied and was found to be highly focused, with one TCR beta-chain sequence tending to dominate the peptide-specific response – clones to this epitope were Vβ13.6.

Country United Kingdom
Assay type Flow cytometric T-cell cytokine assay, Other
Keywords HAART, ART, immunodominance, TCR usage, memory cells
References Weekes *et al.* 2006

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintainance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

CTL CD8+

- This is a trial of a multi-epitope DNA vaccine that included 21 CTL epitopes, which are conserved among clades A,B,C,D and CRFs and are supertype binding peptides of A1, A3 and B7 supertypes. Participants were from US and Botswana.
- The vaccine was safe and well-tolerated, but the rate of CTL induction was low. CD8+ responses (and no CD4+ responses) were detected in 3/26 subjects using chromium release assay and in 2/42 subjects using IFN-γ ELISPOT assay.
- This epitope was included in the vaccine.

Country United States
Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords binding affinity, supertype, vaccine-specific epitope characteristics, cross-presentation by different HLA
References Wilson *et al.* 2003

- 21 supertype-A2, -A3 and -B7-restricted epitopes predicted to be immunogenic by HLA-peptide binding motifs and phenotypic frequency in individuals were recognized by HIV-1 + subjects in ELISpot assays and shown to bind with high affinity to minimum 3 HLA-alleles of the restricting supertype. These epitopes were included in DNA vaccine EP HIV-1090 that avoided immunodominant responses and did not restrict subject immunity to predicted HLA-type when tested in mice. Transgenic mice mounted a vaccine-response similar to that induced by ELISpot assay in humans.
- Epitope IPIHYCAPA of the HLA-B7 supertype bound most strongly to HLA-B*5101 and -B*5401 and also to -B*0702, -B*3501 but not to -B*5301. It was conserved 75% in subtype A, 42% in B, 38% in C and 75% in subtype D. 0/17 HLA-B7 supertype expressing HIV-1 + subjects mounted a positive ELISpot response to Env259.

Species (MHC) human
Country United States
Assay type CD8 T-cell Elispot - IFNγ, Other
References Balamurugan *et al.* 2008

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.
- CTL immune response to consensus sequence HYCAPAGFAIL was elicited in subject 00015.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Last position (10)in the epitope had potentially experienced positive selection. YCAPAGFAIi escape variant was found.

HXB2 Location gp160 (218–226)

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords dynamics, immunodominance, escape, acute/early infection, kinetics, characterizing CD8+ T cells, viral fitness and reversion
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient BORI had high viral loads and rapid CD4 decline. BORI mounted 8 detected responses. BORI did not control viral replication well, and escape mutations occurred early and in most epitopes, 6/7 that were precisely identified.
- Four variants of the CKNVSTVQC epitope were found in the patient BORI. CeNVSTVQC and cCeNVSTVhC came up first, at day 6 from onset of symptoms. The CeNVSTVQC form was the form that persisted, with a second rare variant present at day 35, CgNVSTVQC.These variants were not tested for their impact on escape.

Assay type CD8 T-cell Elispot - IFNγ
Keywords HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism
References Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.

- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-Cw8 restricted epitope, CTNVSTVQC was mutated to CqNVSTVQC in the daughter D2 isolate.

Immunogen HIV-1 infection
Species (MHC) human (Cw*0602)
Country Thailand
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords immunodominance, optimal epitope
References Kantakamalakul *et al.* 2006

- T cell responses in CRF01_AE infected individuals from Thailand were studied.

CTL CD8+

- Fine mapping of the peptide NAKTIIVHL, revealed a novel Cw*0602-restricted epitope.

HXB2 Location gp160 (281–288)
Author Location (C consensus)
Epitope AKTIIVHL
Subtype C
Immunogen HIV-1 infection
Species (MHC) human (Cw*0602)
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression
References Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.
- Mutational patterns in the L8 residue of AKTIIVHL are associated with the presence of the HLA presenting molecule in the host.
- AKTIIVHL not optimized.

HXB2 Location gp160 (281–293)
Author Location Env
Epitope AKTIIVQLTEPVE
Subtype CRF02_AG
Immunogen HIV-1 infection
Species (MHC) human
Country Cote D'Ivoire
Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords subtype comparisons
References Aidoo *et al.* 2008

- Factors affecting cross-subtype immunity were evaluated by west Cote d'Ivoire subjects' INF-gamma ELISpot responses to OLPs from a CRF02_AG candidate vaccine, a west Kenyan subtype A virus and a Thai CRF01_AE sequence. 15 test subject sequences were primarily CRF02_AG or CRF02_AG-like, but also pure subtypes A and D. Cross-reactive responses to Gag as well as Env peptides were seen, though the response magnitude to Env was lower, perhaps due to its greater sequence variation.
- 1 subject responded to peptide AKTIIVQLTEPVE from subtype CRF02_AG.

Vector/Type: protein *Strain:* B clade IIIB, B clade SF162 *HIV component:* Gag, gp120, gp140ΔV2 *Adjuvant:* Complete Freund's Adjuvant (CFA), Incomplete Freund's Adjuvant (IFA)
Species (MHC) mouse
Assay type CD8 T-cell Elispot - IFNγ, CD4 T-cell Elispot - IFNγ, Th support of CTL response, Chromium-release assay
Keywords vaccine-induced epitopes, Th1, Th2
References Gavioli *et al.* 2008

- It was demonstrated that co-immunization with Tat broadens in vivo epitope-specific CD8 and CD4 responses to heterologous proteins and thus can be considered as an adjuvant. Specifically, mice immunized with Gag and Tat, responded to 11 T cell Gag epitopes, 5 more than those detected in mice vaccinated with Gag alone. Mice immunized with Env and Tat, responded to 17 T cell Env epitopes, 12 more than those detected in mice vaccinated with Env alone.
- Co-immunization with Tat specificaly drove Th1 responses and did not affect Th2 responses.
- Both Th1 and Th2 responses against Tat were no significantly affected by co-immunization with Env.
- This epitope was recognized both by mice co-immunized with Env and Tat, and by mice immunized with Env alone.

Species (MHC) mouse (A2)
Keywords vaccine-specific epitope characteristics
References Kiszka *et al.* 2002

- Transgenic mice expressing a HLA-A2/Kb chimeric protein were vaccinated with a full length gp160 or with gp160deltaV3, with the V3 loop deleted. Mice given gp160deltaV3 had a broader immune response than those given gp160, with increased responses to conserved HLA-A2 epitopes in the C1 region of gp120, KLTPLCVTL, and the C-term region of gp41, SLLNATAIAV.
- Greater resistance was conferred by the gp160deltaV3 than the gp160 vaccine to a challenge of vaccinia expressing heterologous gp160 from primary isolates (VI-06 and 89.6), and the resistance was conferred by CD8+ T-cells.
- The most intense CTL responses to the intact gp160 vaccine were directed at three V3 peptides.

HXB2 Location gp160 (291–307)
Author Location Env (292–301 BH10, LAI)

Epitope RPNNNTRKS
Epitope name RS9
Subtype A
Immunogen HIV-1 infection
Species (MHC) human (B*07)
Country Kenya
Assay type Cytokine production, proliferation, CD8 T-cell Elispot - IFNγ
Keywords assay standardization/improvement
References McKinnon *et al.* 2007

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.
- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTs as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 4 variants of this index epitope RPNNNTRKS, RS9, were tested in vitro - RPsNNTRKS, RPyNNTRKS, RPyNNTRqS, RPNNNTRrS. Autologous variants RPNNNTRrg and RPNNNTRtS were also detected. The rare variant RPyNNTRqS, found almost exclusively in clade B HIV (but absent in all subjects in this study), showed both proliferative as well as ELIspot responses. However, the intermediate RPyNNTRKS showed only a slight increase in proliferation but not in ELIspot detection.
- RS9 has previously published restriction to HLA-B*07.

Epitope `RPNNNTRKSI`
Immunogen HIV-1 infection
Species (MHC) human (B*07)
Keywords epitope processing, TCR usage
References Ferris *et al.* 1999; Hammond *et al.* 1995

- The processing of this epitope is TAP1/2-dependent, as are most Env epitopes, and it contains an N-linked glycosylation site that is glycosylated in Env.
- Peptide that had been deglycosylated, a process that changes asparagine (N) to aspartic acid (D) (RPNDNTRKSI) was recognized a 100-fold more efficiently than either glycosylated or non-glycosylated RPNNNTRKSI.
- Position 5 is not involved with HLA B*07 binding, so is probably important for TCR recognition.
- HIV-1 Env epitopes are typically processed by a TAP1/2 dependent mechanism, which involves cotranslational translocation into the ER, glycosylation, export back into the cytosol, and deglycosylation for processing, and retransport into the ER for the association with class I molecules.
- The particular pathway of generating an epitope may have an impact on the presentation of that epitope, quantitatively as well as qualitatively.

CTL CD8+

Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Author Location gp120 (304–318 IIIB)
Epitope RKSIRIQRGPGRAFV
Immunogen vaccine
Vector/Type: virus-like particle (VLP) *Strain:* B clade IIIB, B clade MN, B clade RF, B clade SF2, HIV-2 VLP *HIV component:* Gag, V3
Species (MHC) mouse (H-2^d)
References Kang *et al.* 1999

- Virus-like particles could be formed from HIV-2 gag after deleting 143 amino acids at the C-terminal end – a proline rich region in positions 373-377 was critical to VLP formation.
- CTL responses in BALB/c mice were induced by chimeric gag-V3 particles against the V3 region of HIV-1 clade B isolates IIIB (SIRIQRGRAFVTI), MN (KRIHIGPGRAFYTTK), RF (SITKGPGRVIYATGQ), and SF2 (SIYIGPGRAFHTTGR)

- The vaccine induced CTL were cross-reactive with a broad spectrum of B clade isolates, with the exception of the RF V3 which did not induce CTL.

Immunogen HIV-1 infection
Species (MHC) human
Donor MHC A2
Assay type CD8 T-cell Elispot - IFNγ
Keywords assay standardization/improvement, HAART, ART
References Chitnis *et al.* 2003

- 17 perinatally HIV-1 infected children (0.08-16 years) were evaluated for HLA-A2-restricted IFN-gamma CD8+ CTL responses against 4 immunodominant peptides that carry HLA-A2 epitopes. Two peptides were from gp120 (one at position 112, one from the V3 loop), and one each was from gp41 and Gag. 15/17 patients responded to the Gag peptide, 13/17 to the gp41 and the non-V3 gp120 peptides, and 11/17 responded to the V3 loop. 4 children recognized all 4 peptides.

Immunogen vaccine
Vector/Type: peptide *Strain:* B clade IIIB *HIV component:* V3
Species (MHC) mouse (H-2D^{d})
Keywords binding affinity, Th1
References Ahlers *et al.* 2001

- BALB/c and A.AL were immunized with an Env-peptide vaccine construct containing the CTL epitope P18IIIB and the T helper epitope T1, KQIINMWQEVGKAMYA.
- Substitution of Glu (wt) to Ala in T1, kqiinmwqAvgkamya, caused increased affinity for MHC class II Ek, resulting in the upregulation of CD40L in the responding Th cells, and shifting the response towards Th1. Increased Th responses stimulated DCs to produce higher levels of IL-12, and B7-1 and B7-2, and enhanced CTL responses to P18.
- The modified epitope, T1A, elicited stronger protection against increasing doses of viral challenge with vaccinia expressing HIV-1 IIIB gp120 compared to the wt epitope T1.

Epitope name P18
Subtype B
Immunogen vaccine
Vector/Type: DNA *HIV component:* HIV-1
Species (MHC) mouse (A*0201)
Keywords epitope processing, vaccine-specific epitope characteristics, immunodominance
References Singh *et al.* 2002; Sykes & Johnston 1999

- C3H (H-2k) transgenic mice carrying a fused HLA-A*0201 alpha1 and alpha2 and H-2Dk alpha3 hybrid class I molecule were immunized using an epidermal gene gun with an ubiquitin expression library of 32 plasmids that spanned the HIV-1 genome. Ubiquitin targets the expressed HIV-1 peptides to the proteasome.

CTL CD8+

- A single immunization with the UB-HIV-1 library vaccine induced potent, stable and multivalent CTL responses against all library members.
- Immunodominant epitopes SLYNTVATL (Gag), ILKEPVHGV (Pol), RIQRGPGRAFVTIGK (Env) and AFHHVAREK (Nef) elicited strong CD8+/IFN- responses and stimulated CTL that were functional in a Cr-release assay and against wild type antigen.
- The presence of multiple plasmids HLA-A*0201-restricted CTL epitopes did not decrease CTL immunogenicity, and CTL responses to single peptide immunizations were comparable to responses based on mixtures of either 16 or 32 peptides.

Species (MHC) mouse (A2)
Keywords vaccine-specific epitope characteristics
References Kiszka *et al.* 2002
- Transgenic mice expressing a HLA-A2/Kb chimeric protein were vaccinated with a full length gp160 or with gp160deltaV3, with the V3 loop deleted. Mice given gp160deltaV3 had a broader immune response than those given gp160, with increased responses to conserved HLA-A2 epitopes in the C1 region of gp120, KLTPLCVTL, and the C-term region of gp41, SLLNATAIAV.
- Greater resistance was conferred by the gp160deltaV3 than the gp160 vaccine to a challenge of vaccinia expressing heterologous gp160 from primary isolates (VI-06 and 89.6), and the resistance was conferred by CD8+ T-cells.
- The most intense CTL responses to the intact gp160 vaccine were directed at three V3 peptides.

Country Netherlands
Assay type CD8 T-cell Elispot - IFNγ, Flow cytometric T-cell cytokine assay
Keywords rate of progression, escape
References Geels *et al.* 2003
- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occured sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these eptiopes, but this increased over time.

Species (MHC) mouse (H-2^d)
Keywords Th1
References Uno-Furuta *et al.* 2001

- Peptide immunization usually doesn't elicit a good CTL response because epitopes are not internalized and processed and presented, so vaccination with electric pulsing was tried (i.m. injection followed by 8 electric pulses), to enhance peptide uptake through electroporation.
- BALB/c immunized with HIV P18 or hepatitis C P17 peptides with an electric pulse elicited a CTL response, those that did not receive the pulse did not.
- The CTL response was enhanced by addition of immunostimulatory sequences ISS in the plasmid pCMV-LacZ, that contains hexamers GACGTC, AGCGCT, AACGCT, sequences common in prokaryotic genomes but rare in eukaryotic genomes that elicit Th1 cytokines and result in B cell and T-cell proliferation.
- The CTL response was also enhanced by addition of B7-1 cDNA – the B7 family of proteins transduce co-stimulatory signals through interaction with CD28.

Vector/Type: peptide *Strain:* B clade IIIB *HIV component:* V3 *Adjuvant:* Cholera toxin (CT), GM-CSF, IL-12, IL-18, IL-1α
Species (MHC) mouse (H-2D^{d})
References Staats *et al.* 2001

- Cholera toxin (CT) is a potent adjuvant used in animal studies that is not safe in humans, so combinations of cytokins were used in nasal immunization of BALB/c mice V3 peptides to attempt to replace CT as a potent adjuvant.
- Peptide vaccine induced CTL activity was significantly increased by IL-1alpha , IL-18, and GMCSF given alone as adjuvant, but CT gave more potent CTL activity than any single cytokine.
- Combinations of cytokins could be more potent that CT as an adjuvant. The highest tetramer binding of H-2Dd peptide-specific PBMC after nasal immunization was observed with IL-1alpha plus IL-18 as adjuvant.

CTL CD8+

- Nasal immunization with HIV peptide in the presence of IL-1alpha, IL-12 and GM- CSF induced IFN-gamma-secreting cells in the cervical lymph node, the lung and the spleen, and was associated with upregulation of MHC class II and B7.1 on nonlymphocytes in NALT/nasal mucosal cells.
- Consistent results were obtained for the IIIB and the MN peptides.

References Fujimoto *et al.* 2004

- When BALB/c mice were immunized with recombinant HIV-1 Env gp120 or Influenza HA protein together with polyriboinosinic polyribocytidylic acid (poly (I:C)), an epitope-specific CD8+ class I MHC-restricted CTL response was observed. This response was not observed when LPS was used as adjuvant instead of poly (I:C) indicating activation of cellular immunity by poly (I:C). In the presence of poly (I:C), immature DC presented processed external antigen in association with class I MHC.

Vector/Type: DNA *Strain:* B clade IIIB *Adjuvant:* FLt3 ligand (FL), GM-CSF, IL-12, IL-15, IL-2
Species (MHC) mouse
Keywords vaccine-specific epitope characteristics
References Moore *et al.* 2002a
- Intramuscular immunization of BALB/c mice with DNA vaccines carrying either gp160 or Nef in the expression vector plasmid pNGVL gave different responses – gp160 induced strong gp160-specific CTL and IFN-responses and low-titer humoral responses, and Nef generated humoral (IgG1, IgG2a) responses and IFN-responses but little CTL activity.
- Co-injection of DNA plasmids encoding cytokines and/or hematopoietic growth factors, IL2, IL-12, IL-15, Flt3 ligand (FL), and GMCSF tended to give responses that were enhanced quantitatively, but not altered qualitatively.
- Co-administration of GMCSF most strongly enhanced CTL and IFN-responses against pNGVL-gp160.
- Repeated immunization with pNGVL-Nef failed to induce CTL responses. Co-administration of IL-12 most strongly enhanced humoral and IFNgamma responses.
- FL, which enhances innate immune responses, in combination with IL-2, IL-12 or IL-15 generated with most potent Nef responses.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords dynamics, immunodominance, acute/early infection, kinetics, characterizing CD8+ T cells, viral fitness and reversion
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- This was one of five reasonably strong responses in early infection in the patient WEAU, and the epitope sequence did not vary during the first year of the infection.

Species (MHC) mouse (A2)
Keywords vaccine-specific epitope characteristics
References Kiszka *et al.* 2002

- Transgenic mice expressing a HLA-A2/Kb chimeric protein were vaccinated with a full length gp160 or with gp160deltaV3, with the V3 loop deleted. Mice given gp160deltaV3 had a broader immune response than those given gp160, with increased responses to conserved HLA-A2 epitopes in the C1 region of gp120, KLTPLCVTL, and the C-term region of gp41, SLLNATAIAV.
- Greater resistance was conferred by the gp160deltaV3 than the gp160 vaccine to a challenge of vaccinia expressing heterologous gp160 from primary isolates (VI-06 and 89.6), and the resistance was conferred by CD8+ T-cells.
- The most intense CTL responses to the intact gp160 vaccine were directed at three V3 peptides.

CTL CD8+

- While propagating MVA encoding HIV 89.6 Env, excessively staining foci were studied and found to possess a single nucleotide deletion that conferred upon Env a 115 aa C-terminal truncation. Truncated Env was more highly expressed and so induced higher antibody and CTL responses without compromising its ability for CD4/co-receptor fusion. A similar truncation would be beneficial in MVA-based vaccines.
- To test for CTL response to Env epitopes, peptide P18-89.6A9, IFPFRAFYA , was used as stimulating peptide in Chromium release assays where wild type MVA/89.6 and truncated MVA/89.6T induced similar specific lytic activities. Intracellular staining also showed similar induction of IFN-gamma+; IFN-gamma+, TNF+; and IFN-gamma+, IL-2+ CTLs by both forms of the virus.

References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

- A series of protease and proteasome inhibitors was used to identify elements of the processing pathway of this epitope, called p18, both from within Env and from within a chimeric hepatitis B protein which allows proper processing.
- Lactacystin, a proteasome inhibitor, partially inhibits endogenous processing of p18 epitope suggesting both a proteasome pathway and an additional pathway can be used.
- Both TAP dependent and TAP-independent pathways can be used.
- 1,10-phenanthrolin (metallopeptidases inhibitor) blocks epitope presentation demonstrating metalloproteinase processing in the Tap-dependent pathway.
- The Tap-independent pathway does not involve processing by metalloproteinases.
- This epitope is immunodominant in mice, and is presented by multiple human HLA alleles – it as been suggested that the high processing efficiency of this epitope might result in poor presentation of co-expressed epitopes.

HXB2 Location gp160 (311–320)
Author Location gp120
Epitope RGPGRAFVTI
Immunogen vaccine
Vector/Type: vaccinia
Species (MHC) mouse (H-2^d)
References Hanke *et al.* 1998a; Hanke *et al.* 1998b

- This murine epitope was incorporated into a vaccine of CTL epitopes expressed together including 20 HIV epitopes recognized by humans from 12 HLA types, one murine HIV epitope and three macaque HIV epitopes, delivered in a vaccinia virus Ankara (VVA) construct.
- The murine vaccination was more effective at generating CTL when given i.v. rather than i.m.

Immunogen vaccine
Vector/Type: vaccinia, vesicular stomatitis virus (VSV) *Strain:* B clade HXB2 *HIV component:* Env, Gag
Species (MHC) mouse (H-2D^d)
Keywords immunodominance
References Haglund *et al.* 2002b

- Different HIV strains were used for different regions: Env IIIB, Gag HXB2
- BALB/c mice were vaccinated with rec vesicular stomatitis virus (rVSV) expressing either HIV-1 Gag or Env, or both, and retention of memory responses and recall responses were studied by tetramer staining and IFN-gamma production.
- Seven months after vaccination with Env-rVSV, 6% of the CD8+ cells were tetramer positive for the immunodominant Env epitope; these cells had a memory phenotype, CD44-Hi positive.
- Env in rec vaccinia virus (Env-rVV) elicited a strong recall response, with up to 45% to the CD8+ T-cell population tetramer positive and activated (expressing CD62L-Lo), and capable of IFN-gamma production.
- A prime with Env-rVSV and heterologous boost of Env-rVV gave remarkably high levels of memory cells, with approximately 1/3 of the CD8+ splenocytes being Env specific memory cells 150 days after the boost.
- A Gag-rVSV or EnvGag-rVSV prime and with a heterologous Gag-rVV or EnvGag-rVV boost combination gave 40% tetramer positive CD8+ cells, but the fraction of IFN-gamma producing cells was only about 25%. Still the heterologous vector prime-boost combination showed a profound benefit.
- A HIV-1 protein rVSV prime, rVV boost was a more potent combination than a vector reversal of a rVV prime and rVSV boost.

Vector/Type: peptide *Strain:* B clade IIIB *HIV component:* V3 *Adjuvant:* Cholera toxin (CT), GM-CSF, IL-12, IL-18, IL-1α
Species (MHC) mouse (H-2D^d)
References Staats *et al.* 2001

- Cholera toxin (CT) is a potent adjuvant used in animal studies that is not safe in humans, so combinations of cytokins were used in nasal immunization of BALB/c mice V3 peptides to attempt to replace CT as a potent adjuvant.
- Peptide vaccine induced CTL activity was significantly increased by IL-1alpha , IL-18, and GMCSF given alone as adjuvant, but CT gave more potent CTL activity than any single cytokine.
- Combinations of cytokins could be more potent that CT as an adjuvant. The highest tetramer binding of H-2Dd peptide-specific PBMC after nasal immunization was observed with IL-1alpha plus IL-18 as adjuvant.
- Nasal immunization with HIV peptide in the presence of IL-1alpha, IL-12 and GM- CSF induced IFN-gamma-secreting cells in the cervical lymph node, the lung and the spleen, and was associated with upregulation of MHC class II and B7.1 on nonlymphocytes in NALT/nasal mucosal cells.
- Consistent results were obtained for the IIIB and the MN peptides.

Species (MHC) mouse (H-2D^d)
Assay type Cytokine production, Chromium-release assay
Keywords epitope processing, vaccine-specific epitope characteristics, immunodominance
References Wild *et al.* 2004

- A codon optimized gag DNA vaccine was compared to a myristylation defective gag and p24 alone, both of which lack signals for secretion from transfected cells. Gag-derived immunogens that were secreted as VLPs and those that remained intracellular (p24) each produced strong CTL responses, and neither the size of antigen nor cellular trafficking and localization significantly influenced the strength of humoral and cellular immune activation. The formation and release of VLPs was not essential for eliciting strong CTL. BALB/c mice were given the DNA vaccine by i.m. administration of plasmid DNA for the prime and boost.
- Linking the region encoding the V3 immunodominant epitope to the gag gene did not diminish the response to the Gag p24 epitope A9I, but did enable a response to the V3 epitope.
- Minigenes were made incorporating just 1 epitope, minitopes, carrying 1 of 3 murine class I epitopes linked to the Ad2-E3 protein-derived signal peptide to allow access of the epitope to the ER. Weak induction of cellular immune responses was observed, in contrast to the complex polyprotein.

Epitope name R10I
Immunogen vaccine
Vector/Type: vaccinia *Strain:* B clade IIIB *HIV component:* gp160
Species (MHC) mouse (H-2D^d)
Donor MHC H-2D
Assay type Intracellular cytokine staining
Keywords vaccine antigen design
References Samino *et al.* 2004

- The endogenous processing of the HIV-1 envelope glycoprotein generates several different natural peptidic species presented by the H-2D molecule in infected cells, the 9-, 10-, and 11-mer peptides, GPGRAFVTI, RGPGRAFVTI, and QRGPGRAFVTI. CTL with the same antigenicity could recognize all three forms. The complexity of the binding peptides suggests naturally processed proteins could provide more variety as antigens, stimualting more robust and diverse CTL responses.

Immunogen peptide-HLA interaction
Species (MHC) mouse (H-2D^d)
Assay type Chromium-release assay, Other
Keywords binding affinity, structure
References Nakagawa *et al.* 2007

- To study the critical amino acids of both TCR and MHC that interact with peptide P18-I10 of HIV-1 IIIB, the authors used a series of mutant substituted peptides. Peptides substituted with Ala at various positions showed that positions 322R, 324F and 327I were essential for binding to H2-D^d. Residue 325V was critical for interacting with TCR. By employing D-amino acid derived peptides as mutants in order to avoid charge, size and molecular weight differences, they also show that 325V is necessary for CTL-induced cytotoxic activity. Using two distinct CTL clones and molecular modeling they determined that TCR sequences of CDR1 and not CDR3 critically interact with 325V.
- This 10-residue minimally active peptide lies within the immunodominant epitope, RIQRGPGRAFVTIGK, that belongs to gp160, the hypervariable region of Env. Substituted peptides used in this study were RGPGRAFiTI, RGPGRAFlTI, RGPGRAFaTI, RGPGRAFyTI, RGPGRAFfTI, RGPGRAFhTI, RGPGRAFtTI, RGPGRAFsTI, RGPGRAFeTI,RGPGRAFkTI, RGPGRAFrTI and RGPGRAFpTI. In addition, D-amino acid variants of the residues in parentheses were used - (r)GPGRAFVTI, RG(p)GRAFVTI, RGPG(r)AFVTI, RGPGR(a)FVTI,

RGPGRA(f)VTI, RGPGRAF(v)TI, RGPGRAFV(t)I, RGPGRAFVT(i), RGPGRAF(i)TI, RGPGRAF(l)TI, RGPGRAF(a)TI, RGPGRAF(y)TI, RGPGRAF(f)TI, RGPGRAF(h)TI and RGPGRAF(t)TI.

Assay type CD8 T-cell Elispot - IFNγ, Intracellular cytokine staining, Other
Keywords subtype comparisons, vaccine-induced epitopes, variant cross-recognition or cross-neutralization, antagonism
References Larke *et al.* 2007

- Cross-clade vaccine recognition was studied using either single-, multi or several anatomically separated single-clade vaccines. Limited cross-clade response was seen with single-clade administrations. Multi-clade vaccines gave immune interference (antagonism and original antigenic sin), reducing CTL response. Simultaneously administered but anatomically separated vaccines from clades A, B, C decreased antagonism and increased immune responses.
- No cross-reactivity was seen with epitope variants (iGPGqAFyat, fGPGqAFyTn, iGPGRAFyTt, iGPGqtFyat, iGlGqAlyTt, lGPGqAFyat, iGPGRAFyat, iGPGqvFyrt, mGPGRvFyTt) after immunization with Clade A containing index Epitope H, RGPGRAFVTI.

References Fuller *et al.* 2007

- HIV-epitope, RGPGRAFVTI, was fused to a Heptatis B core antigen (HBcAg) gene in order to improve immunogenicity of an epitope-based vaccine in mice. A vaccine containing hybrid HBcAg-epitope linked to an HIV-specific T helper epitope induced significantly higher responses than a hybrid HBcAG-epitope vaccine which perfomed better than epitope alone. The authors suggest that HBcAg could be a better carrier of foreign epitopes than even Hepatitis B surface antigen (HBsAg) - (previously studied).
- This work also deals with a multi-epitope SIV-based vaccine in non-human primates.

Assay type Cytokine production, proliferation, CD8 T-cell Elispot - IFNγ
Keywords Th1, Th2, genital and mucosal immunity
References Gherardi *et al.* 2003

- Mice were intranasally primed with a recombinant influenza virus A vector that carries HIV-1 Env inserted into its hemagglutinin protein. Boosting was performed intranasally with either influenza-Env or intraperitoneally with two vaccinia virus recombinants expressing the Env protein, VVenv and MVAenv.
- Peritoneal heterologous immunization with VVenv induced a 60-fold higher CD8+ IFN-gamma T cell responses than homologous influenza prime-boost. The intraperitoneal MVAenv boost response was greater than the VVenv boost in the spleen and genital lymph nodes, while the VVenv response gave the highest boost with the intranasal route.
- Mice with increased CD8+-T-cell responses also had a higher Th1/Th2 ratio, indicated by the cytokine secretion profile and the IgG2a/IgG1 ratio.

Species (MHC) human
Country United States
Assay type Tetramer binding, Other
Keywords memory cells
References Ramsburg *et al.* 2007

- The requirement for CD4 T cell help in primary versus memory CTL responses was examined. Since a VSV vector encoding HIV Env was used as vaccine, responses specific to HIV-1 Env epitope RGPGRAFVTI as well as VSV epitope N were tested. Both primary and memory responses to the Env epitope did not require Th help. However, primary CTL responses to Env were 2-3 fold higher in the presence of CD4 T cells, while memory responses were tested until 3 months post-priming. Thus memory CTL maintenance dependency on CD4 T cell help is epitope-dependent.

Vector/Type: modified vaccinia Ankara (MVA) *Strain:* B clade 89.6 *HIV component:* Env
Species (MHC) human
Assay type Intracellular cytokine staining, Chromium-release assay, Other
Keywords vaccine antigen design, co-receptor
References Wyatt *et al.* 2008a

- While propagating MVA encoding HIV 89.6 Env, excessively staining foci were studied and found to possess a single nucleotide deletion that conferred upon Env a 115 aa C-terminal truncation. Truncated Env was more highly expressed and so induced higher antibody and CTL responses without compromising its ability for CD4/co-receptor fusion. A similar truncation would be beneficial in MVA-based vaccines.
- To test for CTL response to Env epitopes, peptide P18-89.6R10, IGPGRAFYAR, was used as stimulating peptide in Chromium release assays where wild type MVA/89.6 and truncated MVA/89.6T induced similar specific lytic activities. Intracellular staining also showed similar induction of IFN-gamma+; IFN-gamma+, TNF+; and IFN-gamma+, IL-2+ CTLs by both forms of the virus.

Species (MHC) mouse (H-2^d)
Assay type Cytokine production, CD8 T-cell Elispot - IFNγ
Keywords Th1
References Gómez *et al.* 2004

- Priming of mice with DNA-TAB vector, a polyepitope string carrying 8 different V3 loop sequences, followed by a booster with VV-TAB or MVA-TAB, induced humoral responses, as well as a CD8+ T-cell response against V3 epitopes from three different subtype B HIV isolates. The highest values of specific CD8+ T-cell response were achieved when priming with DNA-TAB and a DNA vector expressing IFN-gamma, followed by a MVA-TAB boost. The T-cell response was Th1.
- The eight V3 loops were linked with an A-G-G-G-A sequence. The three peptides that elicited a response were LR150, SRGIRIGPGRAIL; MN, RKRIHIGPGRAFY; and IIIB, SIRIQRGPGRAFVTI. These peptides were located at the beginning, middle and end of the polyepitope, indicating all parts were able to be processed. It is not known if there is an H-2d epitope in the other five V3 loop variants that did not elicit a response.

- A vaccine study with B clade Envs in mice was unertaken to assess a subtype-specificity of responses. Four T-cell hybridomas responsive to subtype B envelope proteins were tested against 20 different subtype B envelope proteins and a protein each from subtypes A, C and D. IL-2 production was measured.
- No consistent correlation was found between T cell specificity towards epitopes from a certain (B) subtype or lack of specificity towards other (A, C, D) subtype.
- Not only did T-cell specificity not vary with subtype, but pairwise sequence comparisons of gp120 envelope sequences showed that some US-derived sequences were more similar to sequences from distant countries than to each other.
- Changes in core epitopes, flanking and distant regions, all affected responsiveness of the hybridomas to different subtype Env epitopes, showing that it is not only core changes that can eliminate T cell reactivity to an epitope.
- The above findings were substantiated by database analyses showing that epitope distributions are not necessarily dictated by subtype.
- This paper lists several variants of the epitope above,IIGDIRQAHCNISRE.

Epitope RVLKQVTEK
Epitope name E340-348
Subtype CRF01_AE
Immunogen HIV-1 infection
Species (MHC) human (A11)
Keywords HIV exposed persistently seronegative (HEPS)
References Sriwanthana *et al.* 2001

- This was a study of HIV-1 exposed persistently seronegative (HEPS) female sex workers in Chiang Mai, northern Thailand.
- HLA-A11 is very common in this population, and was enriched among the HEPS sexworkers – weak CTL responses were detected in 4/7 HEPS women, and CTL responses were found in 8/8 HIV+ controls, and 0/9 HIV- women that were not exposed.
- This epitope was weakly reactive in HIV+ control study subject 053 who carried HLA-A11.

HXB2 Location gp160 (340–348)

Epitope RVLKQVTEK
Subtype CRF01_AE
Immunogen HIV-1 infection
Species (MHC) human (A11)
Keywords subtype comparisons
References Bond *et al.* 2001

- HLA-A11 CRF01 (called subtype E in Bond *et al.*) epitopes were identified that stimulated CTL from HIV+ female sex workers (FSW) from Northern Thailand, of whom more than half were HLA-A11 positive.
- 77 possible HLA-A11 epitopes were first defined using EpiMatrix, these were screened for binding to A11 finding and 26 bound, and 12 of these were epitopes for CTL responses from 8 HLA-A11 positive FSWs, six were novel, six were previously identified.
- This is one of the new A11 epitopes identified through the streamlined EpiMatrix method, and 2/8 tested FSWs recognized it.
- This epitope was not conserved in other subtypes, and exact matches were rare.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Position 4 in the epitope had potentially experienced positive selection. TLSkIVTKL escape variant was found.

Assay type CD8 T-cell Elispot - IFNγ, CD4 T-cell Elispot - IFNγ, Th support of CTL response, Chromium-release assay
Keywords vaccine-induced epitopes, Th1, Th2
References Gavioli *et al.* 2008

- It was demonstrated that co-immunization with Tat broadens in vivo epitope-specific CD8 and CD4 responses to heterologous proteins and thus can be considered as an adjuvant. Specifically, mice immunized with Gag and Tat, responded to 11 T cell Gag epitopes, 5 more than those detected in mice vaccinated with Gag alone. Mice immunized with Env and Tat, responded to 17 T cell Env epitopes, 12 more than those detected in mice vaccinated with Env alone.
- Co-immunization with Tat specificaly drove Th1 responses and did not affect Th2 responses.
- Both Th1 and Th2 responses against Tat were no significantly affected by co-immunization with Env.
- This epitope was recognized both by mice co-immunized with Env and Tat, and by mice immunized with Env alone.

Country United States
Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords dynamics, immunodominance, escape, kinetics, characterizing CD8+ T cells, viral fitness and reversion
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- WEAU had a reaction to an eptiope within this peptide, and there was very rapid accumulation of substitutions; variation continued through the last sample collected.

Keywords escape
References Liang *et al.* 2008

- 1100 unique full-length Env sequences were analyzed and the positive selection (PS) pressure determined. The QUASI method was used across Clades A, B, C and D, to find PS sites dispersed across Env.
- Frequency of PS sites is stable over time.
- 25% to 61% PS sites are shared between subtypes A, B, C and D, so it is inferred that immune responses are targeted against the same general regions.
- Significant correlations between PS sites and neutralizing antibody response, helper response, antibody plus CTL response are found. This suggests that the NAb response might be the driving force behind HIV-1 Env evolution.

- PS-free sites that are targeted greatly by NAb and CTL were found. Functional reasons for the lack of positive selection in such regions must exist.
- PS-site-rare regions (conserved regions of Env) were examined for PS, and epitopes located in such regions. Epitope SFNCGGEFF, restricted by HLA-B15, -Cw4, -Cw*0401, -C*0407, is on a region free from positive selection. It is found in Filipino and Taiwanese populations and has no known association with progression to AIDS.

Immunogen HIV-1 infection
Species (MHC) human (A29)
Country Zimbabwe
Keywords escape, optimal epitope
References Liang *et al.* 2008

- 1100 unique full-length Env sequences were analyzed and the positive selection (PS) pressure determined. The QUASI method was used across Clades A, B, C and D, to find PS sites dispersed across Env.
- Frequency of PS sites is stable over time.
- 25% to 61% PS sites are shared between subtypes A, B, C and D, so it is inferred that immune responses are targeted against the same general regions.
- Significant correlations between PS sites and neutralizing antibody response, helper response, antibody plus CTL response are found. This suggests that the NAb response might be the driving force behind HIV-1 Env evolution.
- PS-free sites that are targeted greatly by NAb and CTL were found. Functional reasons for the lack of positive selection in such regions must exist.
- PS-site-rare regions (conserved regions of Env) were examined for PS, and epitopes located in such regions. Epitope SFNCGGEFFY, restricted by HLA-A29 is on a region free from positive selection. It is found in Zimbabwean populations and has no known association with progression to AIDS.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords dynamics, acute/early infection, characterizing CD8+ T cells
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape muations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

Immunogen vaccine
Vector/Type: DNA prime with vaccinia boost, protein *Strain:* B clade 1007, B clade 1035
Species (MHC) human
Assay type Cytokine production
Keywords subtype comparisons, immunodominance
References Brown *et al.* 2006

- A vaccine study with B clade Envs in mice was unertaken to assess a subtype-specificity of responses. Four T-cell hybridomas responsive to subtype B envelope proteins were tested against 20 different subtype B envelope proteins and a protein each from subtypes A, C and D. IL-2 production was measured.
- No consistent correlation was found between T cell specificity towards epitopes from a certain (B) subtype or lack of specificity towards other (A, C, D) subtype.
- Not only did T-cell specificity not vary with subtype, but pairwise sequence comparisons of gp120 envelope sequences showed that some US-derived sequences were more similar to sequences from distant countries than to each other.

- Changes in core epitopes, flanking and distant regions, all affected responsiveness of the hybridomas to different subtype Env epitopes, showing that it is not only core changes that can eliminate T cell reactivity to an epitope.
- The above findings were substantiated by database analyses showing that epitope distributions are not necessarily dictated by subtype.
- This paper lists several variants of the epitope above, GSNNTVGNPIILPCRI.

Keywords HAART, ART, supervised treatment interruptions (STI)
References Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient B displayed the greatest response to epitope B44-AW11(p24) and also responded to A32-PW10(RT) in both PB and LN samples, while a third response against epitope A32-RW10(gp120) was only detected in the LN sample. Patient D displayed the greatest response to B27-KK10 (p24), and also responded to A30-RY11(p17), A32-PW10(RT), A30-KY11(RT), A32-RW10(gp120), and B18-YY9(Nef).

Epitope YAPPISGQI
Immunogen vaccine
Vector/Type: DNA *Strain:* B clade 89.6P, SIV *HIV component:* Env, Gag
Species (MHC) macaque (Mamu-A*01)
Assay type Flow cytometric T-cell cytokine assay
Keywords vaccine-specific epitope characteristics, rate of progression, kinetics, memory cells, characterizing CD8+ T cells
References Davenport *et al.* 2004

- Activation and expansion of antigen-specific CD8+ T-cells shows a delay following infection that allows early viral replication. Until day 10, the kinetics of CD8+ T-cell expansion was the same in vaccinated and control macaques. An increase in virus-specific CD8+ T-cell numbers around day 10 in vaccinated macaques coincides with a slowing in viral replication. This indicates that while cytotoxic T-lyphocyte-inducing vaccines may have a long-term benefit in controling viral replication and preventing disease progression, they cannot prevent infection.

HXB2 Location gp160 (435–443)

Epitope YAPPISGQI
Epitope name p41A
Immunogen vaccine
Vector/Type: DNA *Strain:* B clade 89.6, SIV *HIV component:* Env, Gag *Adjuvant:* IL-2/Ig
Species (MHC) macaque
References Barouch *et al.* 2000; Shen & Siliciano 2000

- Different HIV strains were used for different regions: SIVmac239 Gag and HIV-1 89.6P Env
- Monkeys that received the DNA vaccines augmented with IL-2/Ig were infected when challenged with pathogenic SHIV-89.6P, but had potent CTL responses, stable CD4+ T-cell counts, preserved virus-specific CD4+ T-cell responses, low to undetectable viral loads, and no evidence of disease or mortality by day 140 after challenge – monkeys that got a sham vaccine had high viral load, progressed to disease, and were half were dead by day 140.
- IL2/Ig consisting of interleukin-2 (IL-2) for immune stimulation, and the Fc portion of immunoglobulin G (IgG) for stability, was delivered either as protein or as DNA – both enhance the CTL response to vaccination, DNA IL2/Ig giving the most intense response.
- Responses to a dominant Mamu A*01 gag epitope SIV Gag p11C (CTPYDINQM) and a subdominant epitope HIV-1 Env p41A (YAPPISGQI) were tracked and had good durability prior to challenge, and the higher the prechallenge peak p11C CTL response, the lower the post-challenge viral load.
- No NAb responses were detected in the vaccinated monkeys prior to challenge, and comparable peak NAb titers developed in vaccinated monkeys and control monkeys with preserved CD4+ T-cells.
- Shen *et al.* 2000 is an accompanying commentary.

Keywords vaccine-induced epitopes, Th1, Th2
References Gavioli *et al.* 2008

- It was demonstrated that co-immunization with Tat broadens in vivo epitope-specific CD8 and CD4 responses to heterologous proteins and thus can be considered as an adjuvant. Specifically, mice immunized with Gag and Tat, responded to 11 T cell Gag epitopes, 5 more than those detected in mice vaccinated with Gag alone. Mice immunized with Env and Tat, responded to 17 T cell Env epitopes, 12 more than those detected in mice vaccinated with Env alone.
- Co-immunization with Tat specificaly drove Th1 responses and did not affect Th2 responses.
- Both Th1 and Th2 responses against Tat were no significantly affected by co-immunization with Env.
- This epitope was recognized by mice co-immunized with Env and Tat, but not by mice immunized with Env alone.

Immunogen HIV-1 infection, peptide-HLA interaction
Species (MHC) human
Assay type CD8 T-cell Elispot - IFNγ
Keywords immunodominance
References Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, NWRSELYKY, is similar to human protein peroxysomal acylcoA thioestherase, sequence hNWRSELY.

Keywords dynamics, acute/early infection, characterizing CD8+ T cells
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape muations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

- HLA-A2-restricted HIV-1 CTL epitopes were computationally predicted. Binding affinities for HLA-A*0204, immunogenicity in HLA-A*0201 transgenic mice, and responses to the peptides in 17 HIV-1 infected patients were tested. 31 novel conserved A2 epitopes were detected. An average of 4 epitopes were recognized per patient.
- This peptide was an intermediate A2 binder that did not induce CTL and CD8+ T-cell IFN gamma responses in mice. Responses were detected in 5/17 HIV+ HLA-A2 subjects.

References Thorn *et al.* 2007
- 11 HLA-A2+ (A*0201, A*0220, A*0234 or A*0236), patients' HIV were sequenced. Of 28 epitopes studied, most were conserved and elicited a subdominant CTL response. 9 epitopes in 7 proteins showed T-cell cross reaction. These epitopes were optimized to induce more immunogenic but cross-reacting responses.
- Epitopes in Gag, Pol, Env, Nef were more conserved than epitopes in shorter proteins Vpu, Vif, Vpr and Rev. Most natural epitopes were untargeted or targeted by 1 or 2 patients.
- Env 529 TMGAASITL epitope was found in 3 patients and 5 of them had a CTL immune response to it.
- The epitope TMGAASITL is one of the most frequently targeted and sequence variation was seen in TCR interacting residues.

- Comparative genetic and immunological study was conducted of two subjects - patient DK1 with no viremia for >10 years after transient ART and despite continued sexual contact with patient UG1 (his wife) who was an HIV-1-positive non-controller.
- DK1 and UG1 shared most crossover points of recombination but while DK1 had subtype A1 Env, UG1's Env was subtype D. In the shared subtype A1/D regions, homology between the patients' sequences was 98%.
- Out of 23 conserved HLA-A02 epitopes, HLA-A2+ DK1 produced CTL response and IFN-gamma response only to epitope ILKEPVHGV.
- DK1 produced neutralizing antibody only to homologous isolates. It is suggested that early, transient ART may have resulted in full control of viremia and disease via the very narrow specific CTL response and neutralizing antibody.
- Despite carrying HLA-A2, DK1 did not respond to HLA-A2 Env control epitope TMGAASITL, though it did elicit response in a cohort of 11 other HIV-1 + HLA-A2+ patients.

References Zhao *et al.* 2007
- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher interclade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm et al. [J. Virol. 78:2187-2200 (2004)].
- This peptide, IVQQQSNLLRAIEAQQHL differs from the consensus C sequence IVQQQSNLLRAIEAQQHL at 0 amino acid positions, i.e. the two clades' peptides are identical.

References Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope RAIEAQQHL was predicted to be restricted by HLA B*1501, B*1517, B*5101 and C*0304.

Assay type Cytokine production, proliferation, CD8 T-cell Elispot - IFNγ
Keywords assay standardization/improvement
References McKinnon *et al.* 2007

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.
- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTs as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 5 variants of this index epitope RAIEAQQHL, RL9, were tested - RAIEAQQHm, RAIEAQQqm, RAIEvQQHL, RAIEgQQHL, RAIEtQQHL. The index peptide RAIEAQQHL and variant RAIEAQQHm while being most prevalent, are commonly recognized in ELISPOT but do not elicit proliferation. Conversely, the relatively rare variant RAIEvQQHL had proliferative responses more often than it was recognized by ELIspot.
- RL9 has previously published restriction to HLA-Cw*03 and -B*51.

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

References Frahm *et al.* 2007b

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 2 alleles previously known to be associated (Cw03, Cw15) and 4 additional alleles (A02, A30, B58, Cw04).

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than one clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. VTEEFNMWK responses were detected in 2 women that had Env responses to all 4 clades, and clade A gave the highest responses; a VnEEFNMWK variant was in clade B and D, and the clade C Env carried VnEEFNMWe. One woman also reacted with RAIEAQQHL, the other with KNCSFNMTT. RAIEAQQHL was identical in clades A, B, and D, while C carried RAIEAQQHm.

Assay type proliferation, CD8 T-cell Elispot - IFNγ
Keywords assay standardization/improvement
References McKinnon *et al.* 2008

- To evaluate the use of IFN-gamma ELISpot and proliferation assays, the two were compared in a cohort of HIV-1-infected Kenyan sex-workers. ELISpot does not always correlate with viral load and replication or disease progression. The exclusive use of these assays makes definition of CTL response in disease incomplete, especially for memory T cells.
- Despite assaying for 24 INF-gamma and 41 proliferative responses, only 5 of these responses overlapped in the same subject. 18 peptide-epitopes including 10 epitopes and their variants were used in this study.
- RAIEAQQHL did not elicit proliferation alone in any subject; but elicited ELISpot response in 3 subjects; and both responses in 1 subject.

Epitope RAIEAQQHML
Subtype B
Immunogen HIV-1 infection
Species (MHC) human
Country India
Assay type CD8 T-cell Elispot - IFNγ
Keywords subtype comparisons, computational epitope prediction, immunodominance
References Thakar *et al.* 2005

- PBMCs from HIV-1 infected Indian subjects were tested for HIV-1 Gag (with C clade peptides), Nef (with B clade peptides), and Env (clade B peptides) specific T-cell responses. 5 immunodominant regions conserved across clades were identified in Gag and Nef. 3 antigenic regions were found to be recognized by CTLs in the Indian subjects; these regions were not identified as immunodominant in studies from Africa.
- 26 epitopes were predicted within reactive peptides, of which 90% were clustered in the conserved immunodominant regions of Gag and Nef. 3
- of the epitopes were highly conserved across clades, and 7 novel epitopes were found.
- Epitope RAIEAQQHML had >50% conservation across clades B and non-Indian C, but showed no conservation to subtype A. It is predicted to be restricted by HLA-A*69 or -B*40

References Thorn *et al.* 2007

- 11 HLA-A2+ (A*0201, A*0220, A*0234 or A*0236), patients' HIV were sequenced. Of 28 epitopes studied, most were conserved and elicited a subdominant CTL response. 9 epitopes in 7 proteins showed T-cell cross reaction. These epitopes were optimized to induce more immunogenic but cross-reacting responses.
- Epitopes in Gag, Pol, Env, Nef were more conserved than epitopes in shorter proteins Vpu, Vif, Vpr and Rev. Most natural epitopes were untargeted or targeted by 1 or 2 patients.
- Previously defined Env 565 LLQLTVWGI epitope was found in 6 patients but none had CTL immune responses to it.

HXB2 Location gp160 (565–573)
Author Location Env (731–739)
Epitope LLQLTVWGI
Immunogen HIV-1 infection
Species (MHC) human (A2 supertype)
Keywords supertype, rate of progression
References Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind four of the five HLA-A2 supertypes alleles (A*0201, A*0202, A*0203, A*0206 and A*6802).

Assay type Cytokine production, proliferation, CD8 T-cell Elispot - IFNγ
Keywords assay standardization/improvement
References McKinnon *et al.* 2007

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.
- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTs as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 6 variants of this index epitope ERYLKDQQL, EL9, were tested - ERYLqDQQL, EsYLqDQQL, EsYLKDQQL, ERYLrDQQL, ERYLtDQQL, ERYLsDQQL. EL9 has previously published restrictions to HLA-B*14 and -A*32.

CTL CD8+

Keywords HAART, ART
References Mollet *et al.* 2000

- A panel of 16 epitopes covering 15 class I alleles was tested in 14 HIV+ patients from an unselected Caucasian population treated with HAART, using CD8+ cell IFNgamma production to measure responses.
- In general, during the first month of treatment viral load decreased and frequencies of HIV-specific CTL tripled and broadened – eight new HIV specificities that were not previously detectable were newly detected, as were CMV specific CD8+ PBL – but with continued viral suppression, HIV-specific responses diminished.
- Viral rebounds gave different patterns of response: increases or decreases in pre-existing response, new specificities, or no change.

Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords dynamics, immunodominance, escape, acute/early infection, characterizing CD8+ T cells, viral fitness and reversion
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient BORI had high viral loads and rapid CD4 decline. BORI mounted 8 detected responses. BORI did not control viral replication well, and escape mutations occurred early and in most epitopes, 6/7 that were precisely identified.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Eleven variants in the ERYLKDQQL epitope were found in the patient BORI. ERYLKeQQp came up first at day 17 from onset of symptoms, but wasn't tested for escape properties. ERYLrDQQL came up next, by day 31, but didn't confer escape in a Cr release assay. By day 218, three variants were found, all of which gave a diminished response: ERYLtDQQL, ERYLqDQQL, and ERYLsDQQL. By day 556 a complex mixture was present, also including the ERYLmDQQL variant that gave a further reduction in the response, and many double mutants: ERYLmDQrL, ERYLmDrQL, ERYLmDQlL, ERYLtDQrL and ERYrtDQrL.
- In SUMA, the only variation found in the 24 epitopes was in three overlapping epitopes in Tat, and in this gp160 epitope; variation accumulated early in infection in the Tat epitopes, but this epitope was stable until a sample 736 days post-infection, when only the ERYLqDQQL variant was detected. This variant was not tested with CTL from SUMA, but gave a diminished response in BORI.

- CTL response to this epitope was studied in 5 HLA-B14 positive persons.
- CTL responses were detected in all five, and CTL clones were isolated from 4/5.
- A diverse repertoire of TCRs recognized this epitope, with similar fine specificities.
- 3/5 subjects showed no variation in viral sequence, 2/5 had a dominant variant that resulted in poor recognition, ERYLQDQQL.
- A minor CTL response specific for the ERYLQDQQL could be detected by two individuals, but the major CTL response was to the ERYLKDQQL form even when it was the minority form.
- Some single amino acid substitutions were well tolerated by most of the CTL clones tested, but others, particularly in the center three amino acid positions, abrogated peptide stimulatory activity.

Immunogen HIV-1 infection
Species (MHC) human (B14)
Keywords HAART, ART, TCR usage
References Islam *et al.* 2001

- Transcript frequencies of four CTL clones from patient 115, with a chronic and stable HIV-1 infection, were tracked in a longitudinal study of samples collected 6-11 years post infection: clone M21 and E15 recognize ERYLKDQQL,and clone D87 recognizes variant ERYLQDQQL, and clone p175b recognizes the A2 epitope SLYNTVATL.
- CTL clone M21 uses the Vβ 4, CDR3 VKDGA, Jβ 1.2 TCR beta gene, and clone E15 uses the Vβ 4, CDR3 VEDWGGAS Jβ 2.1 TCR beta gene, and D87 uses Vβ8, ALNRVD, Jβ2.1.
- Responses were stable even through HAART with undetectable viral loads but frequencies varied over time by 100-fold, ranging from 0.012% of the total population for SLYNTVATL at its lowest point to 3.78% for M21, with the relative frequencies of clones shifting over time.

Donor MHC A32, B14, B7
Keywords HAART, ART, supervised treatment interruptions (STI)
References Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (`http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html`) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient A displayed the greatest response to epitope B14-EL9(gp41), a strong response to B7-TL9(p24), and responses to B7-TM9(Nef) and A32-PW10(RT).

CTL CD8+

Species (MHC) human (B14)
Keywords subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance
References Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFNgamma Elispot assays after vaccination of 5 macaques. The response to the Mamu A*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B14)
Assay type Chromium-release assay
Keywords binding affinity, TCR usage, characterizing CD8+ T cells
References Yang *et al.* 2003b

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 4/14 CTL T-cell clones tested were specific for Env EL9. Under conditions of excess peptide (100ug/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 range for Env EL9 was 5,000 - 60,000 pg/ml.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords escape, characterizing CD8+ T cells, optimal epitope
References Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The variant ERYLqDQQL was the only form of the epitope detected over a 6-year period in this person. Elispot reactions were reduced to the autologous form relative to the B clade consensus form, ERYLKDQQL.

Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords subtype comparisons, variant cross-recognition or cross-neutralization
References McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded

CTL CD8+

to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.

- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. ERYLRDQQL responses were detected in 2 women who had Env responses to all 4 clades, and clade A gave the highest responses; a ERYLkDQQL variant was in clade B and C, and the clade D Env carried ERsLkDQQL. The epitope VSGFLALAW was also recognized by 1 of the women.
- HLA-B*5802 was the only HLA common to both women who reacted with ERYLRDQQL, so may be the presenting allele.

References Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

Epitope name RL8
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B27)
Country Netherlands
Assay type CD8 T-cell Elispot - IFNγ
Keywords computational epitope prediction
References Schellens *et al.* 2008

- Peptide prediction programs based on MHC binding, proteasomal cleavage and TAP transport were applied to select novel epitopes absent from the Los Alamos HIV database. 22 novel epitopes were tested by IFN-gamma ELISpot and 19 (11 HLA-B27 restricted, 8 HLA-B57 restricted) induced strong positive responses.
- Magnitude of response generated was similar to that of previously identified epitopes, but the number of individuals responding was lower. This could be explained by less stringent HLA-typing of subjects and perhaps high sequence variability within these novel epitopes.
- RL8, RYLKDQQL, is a known HLA-B27-restricted epitope used as a positive control for eliciting CTL IFN-gamma response.

Assay type CD8 T-cell Elispot - IFNγ
Keywords acute/early infection, early-expressed proteins
References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

CTL CD8+

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay
Keywords rate of progression
References Gray *et al.* 2009

- 47 HIV-1 subtype C infected patients were followed longitudinally to determine whether there was a relation between magnitude and breadth of CTL responses in primary, acute infection (measured by IFN-gamma ELISpot) and disease progression (measured as viral load at 12 months). CTL responses to Nef were dominant (targeting 6 epitopic regions), followed by responses to Gag, Pol, Rev, Vpr, Env, Vpu, Vif and finally Tat.
- Known epitope RYLKDQQLL is HLA-A*2301 and -A*2402-restricted. Response to a peptide containing this epitope was detected in a rapid progressor 12 weeks post-infection.

HXB2 Location gp160 (585–593)

Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Keywords HAART, ART, supervised treatment interruptions (STI)
References Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (`http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html`) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.

- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient C displayed the greatest response to B27-KK10(p24), and in decreasing order also responded to A24-RW8(Nef), B7-IL9(gp41), A24-RL9(gp41), A24-YL8(gp41), and B7-TM9(Nef).

References Montefiori *et al.* 2003

- HIV-1 + patient AC10 underwent early HAART treatment, which was discontinued 1.5 years later. At this timepoint potent NAb responses against autologous virus were detected. Treatment interruption initially induced weak CD8+ responses directed against 5 epitopes. By days 873d and 923d the CTL response had broadened to target 22 epitopes; of these six were fully characterized. Eventually the virus escaped the NAb response, but escape was not accompanied by a rise in viral load, and the authors suggest the virus was contained by the CTL response.

HXB2 Location gp160 (585–593)

Epitope RYLKDQQLL
Epitope name A24-RL9(gp41)
Immunogen HIV-1 infection
Species (MHC) human (A24)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

CTL CD8+

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- In addition to its known HLA association (A24), an additional HLA (A23) was statistically predicted to be associated with this epitope.

Immunogen HIV-1 infection, HIV-1 exposed seronegative
Species (MHC) human (A24)
Keywords subtype comparisons, HIV exposed persistently seronegative (HEPS), immunodominance
References Kaul *et al.* 2001a

- Variants (R)YL(R/K)DQQLL are specific for the A/B clade.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-A24 women, 3/4 HEPS and 10/10 HIV-1 infected women recognized this epitope, and (R)YL(R/K)DQQLL tended to be reactive in HEPS and infected women, RDYVDRFFKTL in infected women only.
- The dominant response to this HLA allele was to this epitope in all 3/4 HEPS cases but in only 4 of the 10/10 HIV-1 infected women.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.

Vector/Type: DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade *HIV component:* p17 Gag, p24 Gag
Species (MHC) human, macaque (A24, B8)
Keywords subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance
References Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFNgamma Elispot assays after vaccination of 5 macaques. The response to the Mamu A*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, escape, immune evasion
References Kemal *et al.* 2008

- An LTNP was followed longitudinally over 6 years and 3 sampling time points, until transition to disease. His HLA were heterozygous and not associated with nonprogressive infection, but 3 alleles were associated with poor clinical prognosis. No attenuating mutations in initial samplings, but an insertion in the V2 loop and continuing CCR5 coreceptor use were found.
- A decrease in IFN-gamma response was seen over time, suggesting CTL dysfunction. An increase in T-cell epitopes targeted (e.g. emergence of YL8, YLKDQQLL and WY20, WKFDSRLAFHHMARELHPEY variants and gain of response to EL9, EIKDTKEAL, NL10, NSNPDCKTIL, AK9, AIFQSSMTK, WM8, WSMVRERM, VT15, WVHHTQGYFPDWQNYT) was seen concomitant with disease progression, reflecting viral replication and/or variants.
- HLA-B*08-restricted autologous epitope YLKDQQLL elicited CTL responses at the earliest time point, with a reduction in response frequency just before disease progression at the second time point. Viral sequencing showed the emergence of an escape variant K3R, YLrDQQLL, between the first 2 ELISpot samplings. By the third time point, neither YL8 sequence was able to elicit an immune response. HLA restriction was predicted in this study based on the patient's HLA alleles and previous publication.

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of

an overlapping epitope of distinct restriction in the recipient. In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.
- The second donor in the study shares A*0101 and B*0801 with his partner. Escape variant ylQdqqll was transmitted, and it reduces binding to B*0801 by 92% relative to YLKDQQLL.

Assay type CD8 T-cell Elispot - IFNγ, Chromium-release assay, Flow cytometric T-cell cytokine assay
Keywords escape, characterizing CD8+ T cells, optimal epitope
References Koibuchi *et al.* 2005
- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The autologous form of the epitope, YLKDQQLL, matched the B consensus throughout the 5-year period of study, except for 1 rare variant at the first time point, YLrDQQLL, and 1 at year 5, YLKgQQLL.

Epitope `YLRDQQLLGIWGC`
Immunogen HIV-1 infection
Species (MHC) human (Cw7)
References Nehete *et al.* 1998a

- Three long-term non-progressors and one asymptomatic HIV+ individual were studied and found to have HLA class I C-restricted CD8+ Env-specific CTLs – Cw7 specific CTL were found against three peptides, including this one.
- HLA-C antigens are expressed on lymphoid cells to a lesser extent, 10% of either HLA-A or HLA-B.
- HLA-C confers protection against lysis by natural killer cells and by non-MHC-restricted effector T cells and Cw7 directly governs this resistance to lysis – the authors hypothesize that pathogens that inhibit antigen expression and class I expression may particularly down regulate Cw7, thus triggering non-MHC restricted killing.

Keywords binding affinity, acute/early infection, early-expressed proteins
References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

Assay type CD8 T-cell Elispot - IFNγ
Keywords HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism
References Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.

- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A2.1 restricted epitope, WLWYIKIFI was the only one mutated, to WLWYIrIFI in the mother M2 isolate.

References Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- In addition to the published restriction above, epitope WYIKIFIMI was predicted to be restricted by HLA A*0203, A*0206, A*2402.

Epitope name VR10(gp41)
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (B7)
Country China
Assay type CD8 T-cell Elispot - IFNγ
References Zhai *et al.* 2008

- 49 ART-naive chronically HIV-1 infected Chinese subjects' CTLs were tested with 413 OLPs in IFN-gamma assays, determining optimal epitopes specific for Chinese Clade B HIV-1 sequences.
- An inverse correlation was found between CTL response and viral load.
- Targeted peptides have lower entropy than peptides that are not CTL targeted. This correlation is independent of HLA-restriction.
- Previously described HLA-B7-restricted epitope VFAVLSIVNR elicited no immune response in Chinese HIV-1 positive subjects as part of peptide LVGLRIVFAVLSIVNRVR.
- Although the tested peptide sequence (LVGLRIVFAVLSIVNRVR) contains the exact sequence of a previously described HLA-B7 optimal epitope, VFAVLSIVNR, none of the 9 HLA-B7 carriers responded to it (author communication and Fig.1).

Epitope IVNRVRQGY
Epitope name IY9 (gp41)
Immunogen HIV-1 infection
Species (MHC) human (A*3002)
References Goulder *et al.* 2001a
- HLA-A*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.
- A rapid method was developed combining ELISPOT with intracellular IFN-γ staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.
- Two individuals were studied: Subject 199 (HLA A*0201/*3002 B*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A*3002/ B53/*5801 Cw4/7) an African-Caribbean.
- In both HLA-A*3002 individuals the response to RSLYNTVATLY was dominant.
- In subject 199 four additional A*3002 epitopes were identified.
- Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41)

CTL CD8+

Author Location Env
Epitope IVNRNRQGY
Epitope name A30-IY9(env)
Immunogen HIV-1 infection
Species (MHC) human (A30)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Species (MHC) human
Country United States
Assay type CD8 T-cell Elispot - IFNγ, Other
References Balamurugan *et al.* 2008

- To check whether unsuccessful vaccines may interfere with normal patient immune response,2 subjects were followed. The first, 00015, was seronegative while receiving vaccination, but later contracted infection. The second, 00016, had temporary sexual contact with subject 00015 and showed symptoms of disease 2 weeks before him. Without treatment, both reached low chronic viremic levels, and showed similar magnitude of immune response.
- Similar immune pressure was seen on viral sequences in both patients, over time in Gag, Pol, Nef.
- Data suggest that the vaccine failed to prime subject 00015 against HIV infection, but it did not impair ability to naturally contain viremia in comparison with infecting subject 00016.
- CTL immune response to consensus sequence IVNRVRQ-GYSP was elicited in subject 00016.

Assay type CD8 T-cell Elispot - IFNγ
Keywords escape, immune evasion, optimal epitope
References Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Last position (9)in the epitope had potentially experienced positive selection. YSPLSLQTr escape variant was found.

Keywords subtype comparisons, variant cross-recognition or cross-neutralization
References McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. ERYLRDQQL responses were detected in 2 women who had Env responses to all 4 clades, and clade A gave the highest responses; an ERYLkDQQL variant was in clade B and C, and the clade D Env carried ERsLkDQQL. The epitope VSGFLALAW was also recognized by 1 of the women; A and C clade were identical, while clade B carried VnGsLiLAW, clade D VnGlsAiAW.

Assay type Flow cytometric T-cell cytokine assay, Other
Keywords HAART, ART, immunodominance, TCR usage, memory cells
References Weekes *et al.* 2006

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintainance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

References Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

Epitope RLRDLLLIVTR
Immunogen HIV-1 infection
Species (MHC) human (A03, A31)
Assay type CD8 T-cell Elispot - IFNγ, HLA binding
Keywords binding affinity, immunodominance, optimal epitope
References Bihl *et al.* 2006

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope RLRDLLLIVTR when restricted by HLA-A03 elicited a magnitude of response of 450 SFC with a functional avidity of 0.5nM and binding affinity of 9.6nM. When restricted by HLA-A31, it elicited a magnitude of response of 450 SFC with a functional avidity of 0.05nM and binding affinity of 3.8nM.

Country United States
Assay type CD8 T-cell Elispot - IFNγ
Keywords supertype, cross-presentation by different HLA
References Frahm *et al.* 2007b

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 2 alleles previously known to be associated (A03, A31) and 4 additional alleles (A02, A74, B44, Cw04).

CTL CD8+

- T-cells were studied for exhaustion and dysfunction in chronic HIV infection. Polyfunctionality of CTL immune response to HIV-1 decreased with persistence of antigen presence over time in chronic infection. CTL exhaustion can thus be halted by reduction in viral antigen load - either by ART or through escape mutations.
- PD-1, marker for activation and apoptosis increases over time, but it decreases when epitope mutations develop. CD127 however, is not impacted by viral escape.
- Epitope QRGWEVLKY varied to lRGWEiLKY in an untreated patient. Previously published HLA-restriction for QY9 is HLA-A1.

- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

HXB2 Location gp160 (787–805)
Author Location (C consensus)
Epitope `QRGWEALKYLGSLVQYWGL`
Subtype C
Immunogen HIV-1 infection
Species (MHC) human (A*2301)
Country South Africa
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression
References Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.

HXB2 Location gp160 (792–806)
Author Location Env
Epitope `GLKYLWNLLLYWGRE`
Subtype A
Immunogen HIV-1 infection
Species (MHC) human
Country Cote D'Ivoire
Assay type CD8 T-cell Elispot - IFNγ, Other
Keywords subtype comparisons
References Aidoo *et al.* 2008

- Factors affecting cross-subtype immunity were evaluated by west Cote d'Ivoire subjects' INF-gamma ELISpot responses to OLPs from a CRF02_AG candidate vaccine, a west Kenyan subtype A virus and a Thai CRF01_AE sequence. 15 test subject sequences were primarily CRF02_AG or CRF02_AG-like, but also pure subtypes A and D. Cross-reactive responses to Gag as well as Env peptides were seen, though the response magnitude to Env was lower, perhaps due to its greater sequence variation.
- 1 subject responded to peptide GLKYLWNLLLYWGRE from subtype A.

Epitope `KYCWNLLQY`
Epitope name KY9 (gp41)
Immunogen HIV-1 infection

Species (MHC) human (A*3002)
References Goulder *et al.* 2001a

- HLA-A*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.
- A rapid method was developed combining ELISPOT with intracellular IFN-γ staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.
- Two individuals were studied: Subject 199 (HLA A*0201/*3002 B*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A*3002/ B53/*5801 Cw4/7) an African-Caribbean.
- In both HLA-A*3002 individuals the response to RSLYNTVATLY was dominant.
- In subject 199 four additional A*3002 epitopes were identified.
- Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41)

Epitope name KIY9
Immunogen HIV-1 infection
Species (MHC) human (A*3002)
Country United States, South Africa
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding
Keywords memory cells
References Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

Epitope name A30-KQY9(env)
Immunogen HIV-1 infection
Species (MHC) human (A30)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

Keywords immunodominance, escape, variant cross-recognition or cross-neutralization
References Draenert *et al.* 2006

- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their seroconversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
- This epitope, QELKNSAVSL (QL10) was restricted by HLA-B*4001. A variant that arose was QELKkSAVSL.

Keywords rate of progression, escape, immune evasion
References Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- Responses to epitope SLLNATAIAV were seen in early chronic infection. This was one of the epitopes targeted by broad HLA-A2-restricted CTL responses.

Keywords vaccine-specific epitope characteristics, immunodominance
References Peter *et al.* 2002

- When HIV-1 peptides were used to vaccinate HLA-A2.1 transgenic A2-Kb mice, strong responses to five peptides were observed when the peptides were given individually, but immunodominance limited the response to some of the peptides when they were given in combination Peter *et al.* [2001]. IL-12 can counteract immunodominance in BALB/c mice, so it was given with the multiple epitope vaccination, and was instead found to specifically eliminate the HLA-A2.1-epitope CTL responses, but not Kb CTL responses. This was possibly a consequence of transient depletion of T-cells, B cells and macropahges in the spleen.

References Altfeld *et al.* 2005

- The most frequently targeted HLA-A2-restricted CD8+ T-cell epitopes in chronic infection were significantly less frequently recognized during primary infection. This epitope was recognized both in acute and chronic infection, but slightly more frequently in chronic infection.

HXB2 Location gp160 (813–822)
Author Location Env
Epitope SLLNATAIAV
Epitope name A2-SAV10(Env)
Immunogen HIV-1 infection
Species (MHC) human (A2)
Assay type CD8 T-cell Elispot - IFNγ
Keywords rate of progression, immunodominance, early-expressed proteins
References Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

HXB2 Location gp160 (813–822)

Epitope SLLNATAIAV
Epitope name SAV10
Subtype B
Immunogen HIV-1 infection
Species (MHC) human (A2)
Country United States
Assay type CD8 T-cell Elispot - IFNγ, Tetramer binding, Flow cytometric T-cell cytokine assay
Keywords superinfection
References Streeck *et al.* 2008b

- Loss of viral replication control by an elite controller after superinfection was found to coincide with rapid recombination events in 2, ∼50 residue regions of Gag and Env that include immunodominant epitopes KK10 (KRWIILGLNK) and CL9 (CAPAGFAIL). Viral escape was seen at both epitopes and consequent CTL responses against the epitope-variants.
- CTL responses to previously described HLA-A2-restricted SLLNATAIAV were seen, post-superinfection and -recombination.

HXB2 Location gp160 (813–822)
Author Location gp41
Epitope SLLNATDIAV
Epitope name gp41 SV10
Immunogen HIV-1 infection
Species (MHC) human (A68)
Keywords binding affinity, subtype comparisons, supertype, computational epitope prediction
References Altfeld *et al.* 2001c

- HIV was scanned for all peptides which carried the A2-supermotif pattern conserved in more than 50% of B clade sequences – 233 peptides met this criteria, and 30 of these bound to HLA-A*0201 – 20/30 bound to at least 3/5 of HLA-A2 supertype alleles tested.
- Three additional previously described HLA-A2 epitopes were added to the set of 20, and 18/22 chronically infected HLA-A2 individuals had CTL that recognized at least one of the 23 peptides (median of 2 and maximum of 6), while 6/12 acute infected individuals recognized at least 1 (median of 1 and maximum of 2)
- This epitope binds to three HLA-A2 supertype alleles: A*6802 (highest affinity), A*0202 and A*0203 (but not A*0201 and not A*0206)
- This epitope did not elicit an ELISPOT response in 22 chronic HIV HLA-A2 infections, but elicited a strong response in 1/12 acute HLA-A2 infections – this individual, AC13, was HLA A*0201/68 B44/14 and also had a strong response to HLA-A2 vpr epitope AIIRILQQL.

Species (MHC) human
Country China
Assay type CD8 T-cell Elispot - IFNγ

Keywords variant cross-recognition or cross-neutralization
References Zhai *et al.* 2008

- 49 ART-naive chronically HIV-1 infected Chinese subjects' CTLs were tested with 413 OLPs in IFN-gamma assays, determining optimal epitopes specific for Chinese Clade B HIV-1 sequences.
- An inverse correlation was found between CTL response and viral load.
- Targeted peptides have lower entropy than peptides that are not CTL targeted. This correlation is independent of HLA-restriction.
- Author defined epitope SLLNATAIAV elicited an immune response in Chinese HIV-1 positive subjects as part of peptide ELKNSAVSLLNATAIAVA. This epitope differs from the previously described HLA-A2-restricted epitope sequence, SLLNATDIAV, at 1 residue, SLLNATaIAV.
- 2 of the 55 HLA-A2 carriers responded to SLLNATAIaV-containing peptide with average magnitude of CTL response of 270 SFC/million PBMC (author communication and Fig.1).

Keywords assay standardization/improvement, HAART, ART
References Chitnis *et al.* 2003

- 17 perinatally HIV-1 infected children (0.08-16 years) were evaluated for HLA-A2-restricted IFN-gamma CD8+ CTL responses against 4 immunodominant peptides that carry HLA-A2 epitopes. Two peptides were from gp120 (one at position 112, one from the V3 loop), and one each was from gp41 and Gag. 15/17 patients responded to the Gag peptide, 13/17 to the gp41 and the non-V3 gp120 peptides, and 11/17 responded to the V3 loop. 4 children recognized all 4 peptides.

Epitope `LLNATAIAV`
Immunogen HIV-1 infection
Species (MHC) human (A*0201)
Keywords binding affinity
References Kmieciak *et al.* 1998a

- CTL responses in six patients to four Env epitopes were studied: D2: LLNATAIAV, 5.3: RLRDLLLIV, D1: KLTPLCVTL, and 4.3: QMHEDIISL—all have A2 anchor residues.
- The C terminal epitopes (D2 and 5.3) were highly variable and the variability was considered responsible for limited CTL response, while D1 and 4.3, N-terminal epitopes, were much more conserved and gave evidence of high levels of CTL response *in vitro*.
- Peptides 5.3 and D2 bound to HLA A*0201 with low affinity and were variable, particularly D2.
- Substitutions in peptide D2: llnTIaiav did not abrogate the response, but diminished it.
- In a longitudinal study, the CTL response to the variable D2 epitope diminished over time, while the response to the conserved epitope D1 stayed higher.

Assay type CD8 T-cell Elispot - IFNγ
Keywords HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism
References Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A2/A*0201 restricted epitope, LLNATAIAV was mutated to LLNAiAIAV in the daughter D2 isolate.

Assay type CD8 T-cell Elispot - IFNγ
Keywords characterizing CD8+ T cells
References Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.

- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

Keywords dynamics, immunodominance, acute/early infection, kinetics, characterizing CD8+ T cells, viral fitness and reversion
References Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape,within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- This was one of five reasonably strong responses in early infection in the patient WEAU, and the epitope sequence did not vary during the first year of the infection.

Species (MHC) mouse
Assay type CD8 T-cell Elispot - IFNγ, T-cell Elispot
Keywords assay standardization/improvement, vaccine-specific epitope characteristics, vaccine antigen design, antibody generation
References Karpenko *et al.* 2007

- A combined VLP-based vaccine, CombiHIVcac, was designed comprising TBI with 4 T-cell epitopes and 5 B-cell epitopes, as well as TCI with over 80 T-cell epitopes from Env, Gag, Pol and Nef conserved across A, B and C HIV-1 subtypes. The vaccine induced humoral and cellular immunity in mice infected with 3 HIV-1 strains. Virus-neutralizing activity was as efficient as HIV-1 patient sera inhibition of viral replication. IFN-gamma and IL-2 ELISpot showed that CTL responses were induced, though at 2 and 10 times lower than T-helper responses as measured by IL-4 ELISpot. Toxicity studies showed the vaccine to be promising with no allergenic properties.
